The anti-bacterial action of sulphonamide compounds is highly selective. Only certain bacteria are susceptible, and it is therefore irrational to treat an infection with such compounds unless it is known in advance that one of these bacteria is responsible. Even susceptible bacteria respond differently to the treatment: some can be inhibited by small doses over a short period, others require larger dosage and a longer administration. Moreover, the response of any one organism is inconstant, some strains being more susceptible than others, and even the susceptibility of an individual strain in the same patient sometimes seems to vary from time to time. Other factors apart from variations in immunity and bacterial sensitivity influence the response to sulphonamide chemotherapy. Thus to obtain optimum results it is necessary to maintain

the concentration of these compounds in the body at an effectively bacteriostatic level throughout their administration. The more potent of these compounds are very diffusible, and are excreted almost as rapidly as they are absorbed. To maintain an effective concentration they must therefore be given in adequate doses, properly "spaced," and the administration must be uninterrupted. Inadequate dosage and too short a period not only fail to do any good but seem to lead to the development of acquired resistance on the part of the organism to the drug ("sulphonamide-fastness"), which may produce complete non-response to subsequent chemotherapy, however intensive this may be.

To attack a bacterial focus the sulphonamide must be brought to it by the blood stream: an adequate blood supply to an infected area is therefore essential to success. I have seen many failures of chemotherapy attributable to the presence of avascular foci, such as infected blood-clot (for example, in thrombosed veins and cardiac vegetations), patches of necrotic tissue, abscesses embedded in fibrous tissue or sclerosed bone, and infected areas with local vascular failure following venous stagnation, thrombosis; or pressure by an inflammatory exudate. In some of these cases success was ultimately obtained by improving the blood supply of the focus with such measures as physiotherapy or surgical relief of tension. Finally, no chemotherapeutic agent can deal with an infection from an unlimited source of bacterial contamination, however sensitive the bacteria may be. Thus, it is futile to treat a general peritonitis with sulphonamide when there is a source of continuous infection, such as a perforated appendix or strangulated loop of intestine, unless this has been previously removed.

The number of bacteria now known to be sensitive to sulphonamide compounds already includes the following: haemolytic streptococci, certain non-haemolytic streptococci (for example, *Strep. viridans* and *Strep. faecalis*), *B. coli* and other members of the coliform group, certain pneumococci, the gonococcus, the meningococcus, and probably certain anaerobes, such as *Cl. welchii*.

Sulphonamide Compounds and their Nomenclature

Thus far I have made a trial of eight sulphonamide-containing substances. Although these do not constitute all the sulphonamide compounds manufactured to date, they are the best known and most thoroughly investigated of them. Much uncertainty exists in the minds of practitioners as to the nature of these compounds, partly on account of their complicated chemical structure but also because of the confusing and unnecessarily involved nomenclature adopted by manufacturers. The essential chemistry of these compounds is not difficult to understand. They all contain at least one benzene group (C_6H_5 , shown usually in the form of the benzene ring , at least one amino group (NH_2), and at least one sulphonamide group (NH_2SO_2). If we start with benzene and add an amino (NH_2) group to it we obtain aminobenzene ( NH_2), which is the chemical name for aniline. By attaching a sulphonamide group (NH_2SO_2) to the side (para) of aminobenzene, we obtain para-aminobenzenesulphonamide (NH_2SO_2 ,  NH_2). A shorter name for this is obviously aniline sulphonamide, which has been further abbreviated

to "sulphanilamide"—and so we arrive at the simplest and best known of all sulphonamide compounds. The other compounds are either modifications of sulphanilamide or substances with a more complicated chemical structure, but they all contain the above three groups.

Sulphanilamide (para-aminobenzenesulphonamide).—This is the compound which until quite recently has shown the greatest bacteriostatic potency and the widest anti-bacterial range. It is mostly manufactured in the form of oral tablets ($7\frac{1}{2}$ grains or 0.5 gramme), but unfortunately under so many different trade names that much confusion has arisen over its nomenclature. "Sulphanilamide" and "para-aminobenzenesulphonamide" are the only chemically correct names for it, but it is sold by various British and foreign firms under the following synonyms: sulphonamide-P, streptocide, prontosil album, colsulanyde, P.A.B.S., and prontylin. All these names refer to the same drug—sulphanilamide. An extremely diffusible substance, it is rapidly excreted in the urine, in which it can be estimated by a simple quantitative test. Sulphanilamide arrests the growth of all sulphonamide-susceptible organisms with the exception of the pneumococcus, but it is apt to cause certain toxic effects. Its effective dosage and period of administration vary with the causative organism, the weight of the patient, the site and nature of the infection, and the degree of immunity. Sulphanilamide has the advantage of being very considerably cheaper than most of the other sulphonamide compounds.

T 693.—Recently a compound of sulphanilamide and pyridine (para-aminobenzenesulphonamido-pyridine) has been introduced by Messrs. May and Baker (at present known as T 693), which shows a bacteriostatic potency at least equal to that of sulphanilamide and a wider anti-bacterial range, since it acts on pneumococci as well as on the other susceptible organisms. Unfortunately, in my hands it has proved even more toxic than sulphanilamide.

The Prontosil Drugs.—Prontosil rubrum (oral tablets) and prontosil soluble (by injection) are the original compounds (Bayer) with which the new chemotherapy started. They are highly complicated chemical substances, their full names being diamino-azo-benzol-sulphonamide (prontosil rubrum) and disodium-acetylaminooxynaphthalenedisulphonate (prontosil soluble). Although their action is similar to that of sulphanilamide (into which they are partly converted in the body), their anti-bacterial range and potency are less extensive. But they have the advantage of being less toxic, and I have found prontosil soluble (in doses of 10 to 30 c.cm. of the 5 per cent. solution daily) particularly useful in major operation cases.

Proseptasine and Soluseptasine.—These drugs (May and Baker) are the least toxic of all the sulphonamide compounds. Unfortunately they also appear to be the least potent and to have the narrowest anti-bacterial range. Proseptasine (oral tablets) is a benzyl derivative of sulphanilamide (para-benzylaminobenzenesulphonamide), while soluseptasine (for injection) has a very complicated structure (disodium-phenylpropylaminobenzenesulphonamido-disulphonate) in some respects similar to that of prontosil soluble.

Uleron.—This compound (Bayer) is given in the form of oral tablets, and is much thought of in Germany; it differs from all the above in having two sulphonamide groups (disulphonamide). I have used it in some 200 cases of gonococcal, streptococcal, and coliform infections, and have found it relatively free from immediate toxic effects. Its anti-bacterial action, however, has proved very capricious, and one cannot help thinking that this may

in part be due to its low solubility in neutral media, and probably, therefore, to its relatively poor diffusibility. Striking clinical improvements have followed its administration, but a rather low proportion of bacteriological cures.

Rubiazol.—At present I am making a trial of this compound (carboxy-sulphonamido-chrysoidine), made by Messrs. Roussel and extensively used in France. It appears to be relatively non-toxic, but I am not yet able to speak authoritatively of its anti-bacterial range or effectiveness.

Toxic Effects of the Compounds

On the whole it seems that the more effective a sulphonamide compound is against bacteria the more toxic it is to man. Thus, sulphanilamide and T 693, the two compounds which have shown the highest potency and widest anti-bacterial range, have also produced the highest incidence of toxic by-effects. These toxic effects may be divided into three groups, according to their severity and importance:

(a) *Mild*—of no significance, and not indicating cessation of the chemotherapy.—These are extremely common, and include headache, giddiness, muscular weakness, loss of energy, and other nervous symptoms; nausea, anorexia, and constipation; slight cyanosis, chilliness, palpitations, slight dyspnoea, and mild urticarial rashes. Fortunately, most of these symptoms tend to pass off after the first few days, owing to the development of tolerance to the drugs. Also, they can be mitigated to some extent by rest and fresh air, by cutting down the ingestion of sulphur, and by giving glucose and free fluids.

(b) *Moderate*—of no serious significance, but usually demanding cessation of the chemotherapy.—These occur in about 10 per cent. of patients taking sulphanilamide, and include vomiting, diarrhoea, prostration, mental changes, fever, extensive skin rashes (morbilliform and scarlatiniform), oedema, and marked cyanosis, pallor, or dyspnoea. The last three symptoms always indicate a complete examination of the blood.

(c) *Serious*—demanding immediate cessation of chemotherapy, repeated blood examinations, and appropriate therapeutic measures, which should include an attempt to get rid of any sulphonamide in the intestine by colonic wash-outs. The serious effects are: (i) destructive blood changes—for example, agranulocytosis and haemolytic anaemia; (ii) extensive purpuric rashes with high fever; (iii) toxic jaundice; (iv) toxic nephritis. In 1,500 cases I have seen only six examples of these serious effects, all of them recovering completely. I have yet to experience a case of agranulocytosis or other serious blood damage.

The other sulphonamide compounds have produced very little in the way of immediate toxic effects, but one of them—uleron—has the unique property of occasionally causing a peripheral neuritis. This does not occur unless the drug is given continuously over a period of more than seven days.

Gingivitis and Pyorrhoea

This disease is primarily a streptococcal gingivitis, and although there are many predisposing causes the teeth themselves may be quite sound. It starts with redness, swelling, and tenderness of the gums, which become spongy and bleed easily. The disease may be partly arrested at this stage, or it may pass on to suppuration and a genuine pyorrhoea. The infection of the gum becomes associated with a rarefying osteitis of the alveolus, leading to absorption of bone, and so to exposure, loosening, and finally casting off of the teeth. Conservative treatment, thus far, has been very unsatisfactory, as is shown

by the frequent use of such radical procedures as wholesale dental extraction and gingivectomy.

Some eight months ago, through the courtesy of Professor A. Fleming, a number of cases were investigated at St. Mary's Hospital in a research undertaken with Dr. C. W. Morley. It was found that the outstanding organisms were *viridans* streptococci, while haemolytic streptococci and other bacteria were less often discovered. We then started to treat cases with sulphonamide compounds, under full bacteriological control. We have succeeded, after many disappointments, in evolving a technique which yields a high proportion of excellent results, both clinically and bacteriologically, provided the cases are treated before there is loosening of the teeth or serious retraction of the gums.

Smears and cultures are taken at the start of treatment, and weekly afterwards. For the first two or three weeks the patient is given injections (twice weekly) of a parodontal streptococcal vaccine, which are continued for a minimum of six weeks. Sulphonamide chemotherapy is started in the third or fourth week. Relapses are very common after only one course, and it was found that at least three 14 to 21 day courses had to be given (with intervals of two to four weeks) to obtain lasting improvement. Most of the cases have been given sulphanilamide (2 to 4 grammes daily), but we are now using T 693 with equally promising results. No local treatment is employed.

Ulcerative Stomatitis and Pharyngitis

During the work mentioned a number of cases were seen of chronic and relapsing septic ulcers of the mouth, palate, and pharynx, from which *viridans* or haemolytic streptococci were obtained on culture. They all responded to sulphonamide therapy clinically and bacteriologically in a matter of days, but most of them relapsed afterwards. We are now treating them along the same lines as the gingivitis cases—that is, with multiple courses of sulphanilamide and vaccine—and the good results appear to be much more lasting. Quite recently I obtained complete resolution in two days of a large acute streptococcal ulcer of the fauces with severe oedema. Sulphonamide chemotherapy would also seem to be worth trying in cancerum oris.

Acute Tonsillitis

My experience with sulphonamides in this condition is limited to cases of follicular (streptococcal) tonsillitis, Vincent's angina, and quinsy. The Vincent's angina cases failed to respond, but the follicular and suppurative tonsillitis resolved in twenty-four to forty-eight hours, although the actual follicles in follicular cases persisted for several days. Three of the follicular tonsillitis cases relapsed after only two days' treatment, and I now continue the chemotherapy for at least five days. All that the treatment seems to do in these acute cases is to hasten recovery, but one is perhaps justified in hoping that it may also prevent such complications as a septic adenitis or rheumatism. Quite moderate dosage of sulphanilamide (1.5 to 3 grammes daily) appears sufficient to overcome the infection, while the less toxic sulphonamides (for example, uleron or proseptasine) produce an equally striking, if a trifle slower, clinical improvement.

Sinusitis

Thus far I have treated three cases of chronic maxillary sinusitis and one of ethmoiditis with sulphonamides. Two of the maxillary cases were bilateral, of many years'

standing, and had had several operations. Streptococci were obtained on culture, and both patients were ultimately made well, although one required no fewer than five courses of sulphanilamide and the other three courses. The third maxillary case, also very chronic, gave a growth of pneumococci as well as streptococci, and was treated with T 693 after preliminary vaccine. He improved rapidly, but was very intolerant to the drug; subsequently he was given two courses of sulphanilamide, and is now quite free from symptoms. The case of ethmoiditis (streptococcal) showed no response to a longish course of sulphanilamide, but there was extensive necrosis of the skull before the chemotherapy was begun.

The first three cases suggest that chemotherapy can influence even the chronic relapsing type of sinusitis. I do not know how long these patients will remain well, but I believe that repeated chemotherapy combined with vaccine will at least make relapses less frequent. As yet there has been no opportunity of treating primary acute sinusitis, but one has every reason to believe that it would respond more easily and more permanently than the chronic variety.

Otitis and Mastoiditis

Sulphonamide chemotherapy has already established itself as a valuable adjunct in the surgical treatment of these conditions; it has also proved of life-saving value in the streptococcal meningitis which may occur as a complication. But it cannot be stated too strongly that no anti-bacterial remedy should be used as an alternative to operative drainage of a suppurating focus in regions as dangerous as the tympanum and mastoid.

(To be continued)

THE PHYSICAL BASIS OF ALCOHOLIC MENTAL DISORDERS

LECTURE BY PROFESSOR MAPOTHER

The seventeenth Norman Kerr Memorial Lecture was delivered at Friends House, Euston Road, on October 11 by Professor EDWARD MAPOTHER, professor of psychiatry, University of London. The chair was taken by Mr. Arthur Evans, F.R.C.S., president of the Society for the Study of Inebriety, under whose auspices the lecture is instituted.

Professor Mapother, discussing first of all the questionable results of alcohol, said that some findings appeared to support the conclusion that the expectation of life among insured persons was greater for abstainers than for even moderate drinkers. But it was uncertain how far this might be due to the fact that the so-called moderate was in reality immoderate at the time of insurance or became so subsequently. On the other hand, many of the most cherished beliefs of popular medicine as to the value of alcohol had gone, such as that, for instance, it kept out the cold, or formed a suitable ingredient of cooling drinks in summer. There seemed to be no foundation for the belief that it was indispensable to avert tropical infections or to ward off chill. The least justifiable of all kinds of drinking was drinking "by doctor's orders."

On the possible value of alcohol as a food, Sir Frederick Gowland Hopkins, as reported in the *British Medical Journal* of December 11, 1937 (p. 1184), had pointed out that experiment did not indicate that muscular exercise increased the rate of combustion of alcohol, which was the real issue. While alcohol was certainly destroyed

and oxidized in the blood, and thus produced heat, there was no proof that it entered into the metabolism of the muscles in the sense that sugar did. That, if a food at all, alcohol was a bad one could not be doubted.

Alleged Stimulating Effect of Alcohol

Turning to effects which beyond question did originate in the taking of alcohol to excess, Professor Mapother said that it was doubtful whether in man alcohol in any concentration ever really produced a true stimulation. In very low concentrations and in some persons relatively simple automatisms such as typewriting might show a minor degree of improvement, though even here it seemed likely that the apparent activation was in reality reduction of inhibition; but in all higher mental activities involving any degree of discrimination or any type of voluntary action, reduction of efficiency was universal, even with doses which were called moderate. To say that the effect of alcohol was reduction of inhibition was not necessarily to condemn its use in all circumstances. Alcohol, which was, of course, liable to lead to many accidents, also mitigated their shock; it was proverbial that drunken men might perform astonishing feats after sustaining a fracture. Alcohol had its use for operations before more effective anaesthetics were introduced; it not merely dulled the consciousness of the patient, but actually preserved him from the shock, which might have been fatal. None of these apparently beneficial effects constituted any sufficient justification for alcohol, because in every instance there were better ways of achieving the same end.

The initial taking of alcohol in the ordinary way was in the vast majority of cases for the production of pleasure. Addiction might arise by this becoming habitual, and then the motive became less clearly conscious. Later the person became conditioned so that for more and more situations having a few drinks was an automatic response. Even so far as "normal" people were concerned psychological explanations in many cases seemed inadequate, and a more likely theory was the periodic occurrence of a state of discomfort of biochemical origin which the individual had learnt could be allayed by alcohol.

"It is not uncommon in extremely able and well-balanced men living vigorous and useful lives to find that suddenly and out of the blue, without the least plausible explanation of a psychological kind, they are affected with a crisis of anxiety lasting several days. This may occur on the day after having dined not wisely but too well. And they are apt to correct it with a hair of the dog that bit them. The occurrence of a somewhat similar kind of crisis and the discovery of alcohol as the fatal antidote for this recurrent discomfort seems the most plausible explanation of the way in which many men, otherwise of the highest character and greatest efficiency, ruin their lives by a quite occasional bout of drunkenness."

The lecturer thought that this discomfort might be dependent upon the presence of adrenaline in excess, to which alcohol was antagonistic.

The Problem of Addiction

In discussing the addiction of those who eventually developed mental syndromes Professor Mapother distinguished between the cases in which the syndrome was an organic one due to alcohol and those in which it was not. There was little ground for belief in any quite specific craving for alcohol. Moreover, the strictly periodic dipsomania of which one read and heard from patients rarely stood examination. Among convalescent alcoholics while in hospital such crises of aggravated craving or anxiety as must then occur if they were true dipsomaniacs were practically never seen. Perhaps, as had recently been maintained, the periodic craving for alcohol was not a primary but a tertiary condition following upon occasional and then steady drinking.

Several physical explanations of acquired tolerance were conceivable. It might depend upon change in the per-

meability of the cell membranes and neurons; on a varying resistance of the barrier between the blood and the neuron; or upon the development in the blood of an antibody, biologically if not chemically forming an antidote to the action of alcohol. Actually the only demonstrable change was delayed absorption. The effect of alcohol on motor and still more on mental functions was variable, and the distinction between ordinary and pathological drunkenness entirely artificial. Somewhat less than 1 per cent. concentration in the blood was usually fatal. This concentration would be reached by the taking of one pint of absolute alcohol (for example, as two pints of whisky or brandy) within one or two hours.

Alcoholic Neuritis

Of the chronic effects of alcoholism the lecturer dealt in most detail with the nervous lesions of chronic neuritis; the lesions, by the way, in this condition were practically identical with the distribution of the nervous lesions in beriberi. In cases usually seen in this country it was notable that the distal parts of the legs were most affected. In a well-marked case there appeared to be a special affinity of the cause (whatever the cause was) for the lower sensory neurons. Thus appreciation as such of a painful stimulus—for example, a pin-point—was often lost before the awareness of a touch. Somewhat later than afferent changes, affection of the lower motor nerves of the anterior tibial group was usual, with characteristic foot-drop and "steppage" gait. On the other hand, that there might be affection of the lateral columns by chronic alcoholism was shown by the fact that before reflexes were abolished by impairment of proprioceptor or lower motor neurons there was often marked exaggeration of tendon jerks. This persisted throughout in many cases of Korsakow's psychosis without gross neuritis.

Of late years evidence had been steadily accumulating that the proximate cause of alcoholic neuritis was not the contact of the alcohol itself with the neurons. The action of the alcohol was indirect, bringing about shortages similar to those responsible for the nervous conditions in beriberi and other deficiency diseases. It had also been shown that if considerable doses of vitamin B₁ were given recovery from neuritis occurred, although the patient was still taking large amounts of whisky.

The lecturer went on to stress the frequency with which the syndromes which followed the damage done by alcoholism were combined or changed by transition into one another or alternated in different stages of one attack. This suggested that there was fundamental unity in their causation, and that their broader differences were probably anatomical and biochemical.

In alcoholic psychoses the predominant abnormalities were confusion, hallucinations, and amnesia for recent events. As a speculation it might be suggested that in all these conditions the system predominantly affected was a proprioceptor chain of which the lowest links were those neurons subserving sensation from muscles and joints. In Korsakow's psychosis the mood was often euphoric; in all the other syndromes there tended to be predominance of unpleasant feeling. It was a striking fact that in contrast with the euphoria for which drink was taken the mood of the psychosis resulting from chronic alcoholism was usually one of intense anxiety.

Professor Mapother concluded with some remarks on the social aspects of alcoholism, and ventured the opinion that in this country a larger measure of restriction would improve matters. Prohibition in the United States, although it broke down, largely owing to failure of co-operation between the authorities, lowered the incidence of alcoholic consequences to a level never previously approached. Prohibition might score even greater successes, here, but it was not likely to come about, because of the respect for individual liberty which for good or ill was the chief contribution of this country to the world.

Nova et Vetera

THE ENGLAND OF LETTSON

In his presidential address to the Medical Society of London on October 10 Dr. C. E. LAKIN suggested that after the tension of recent weeks it might be a relief to turn the thoughts to the placid eighteenth century, the century in which the Society was founded, a period which had been regarded as the most serene and unimpassioned in the history of England. One looked back with longing, he said, to those days of quiet, when everything seemed to have settled down to a stable equilibrium—when the old man saw in his age the things he had seen in his youth. Under the spell of such recollections there seemed to be some excuse for regarding that century as a happier one than our own. How beautiful, for example, were the furniture and trinkets of the period! From these, as well as from the paintings and mezzotints, something of the spirit of the time could be caught. One compared them with our own mass-production to the disadvantage of the latter. In Georgian days the English landscape could be seen in all its beauty, and if a building was observed it enhanced the scene.

Dr. Lakin then proceeded to give an interesting illustrated account of the English countryside in the eighteenth century—its village life, its agriculture, economics, and transport. He also described the town, with its shops and streets, with the gibbets still standing in the Edgware Road, and the "resurrection men" still at work in a burying ground in Tottenham Court Road; also with the coffee-houses, of which there were nearly 3,000 in London at the beginning of the eighteenth century. Child's coffee-house in St. Paul's Churchyard was, along with another in Cornhill, the favourite one for members of the College of Physicians, and there the physicians met the apothecaries. It was at a coffee-house that Radcliffe received the summons to hurry to St. James's to see Queen Anne, and sent a message that lost him his Court appointment, "Tell Queen Anne her distemper is nothing but vapours. She is in as good a state of health as any woman breathing, only she cannot make up her mind to believe it."

Harley Street in the Eighteenth Century

It was in the eighteenth century that Harley Street and the adjacent thoroughfares around Cavendish Square were built. Upper Wimpole Street, Devonshire Street and Place, and Beaumont Street occupied the site of the once famous Marylebone Gardens. Where Welbeck Street now stood there was an old inn where it was customary to examine pistols before setting off for the dangerous journey to Lisson Fields (now Lisson Grove), then a part of the village of Paddington. The pageant of the streets, Dr. Lakin continued, must have been made more vivid by the presence of medical students. Richard Smith, surgeon to Bristol Infirmary, had left a record of minute details of the dress and appearance of many of his medical contemporaries. He gave the following description of a fellow-student of his in the Borough, attending Guy's and St. Thomas's. His hair was pomatumed, powdered and frizzed, and tied behind in a tail. He had a large cravat with a muslin "cascade" in front, in which was a brooch. He wore a fancy figured short waistcoat, a pair of yellow breeches reaching halfway down his calf, blue silk stockings, and brass buckle shoes with false straps. A student in the Borough in 1765 on one occasion went to a confinement wearing a scarlet coat and carrying a sword. He was stopped by Dr. Colin Mackenzie, who pointed out to him the impropriety of a man going armed to bring a being into the world, the sword being generally used to send someone out of it.

Medical London of the Time

Concluding with some references to medical London in the second half of the eighteenth century, Dr. Lakin said that when William Hunter came to the metropolis in 1741 there were six hospitals. His own hospital—Middlesex—which Hunter joined in 1748, was launched by public subscription in 1745. Physicians abounded at that time, but only two surgeons of mark were alive. One was Cheselden, who was quite an old man, and the other was Percival Pott, who was in his prime. Physicians like Sir Hans Sloane were men of great learning, but more at home in literature and philosophical discussion than at the bedside. The greatest among the physicians was Mead, who was carried by a coach and six from his country to his town house. Scientific medicine might be said to date from 1761, a year which was memorable for the publication of two books, one of them Morgagni's great work which made pathological anatomy a science, and the other a work of Leopold Auenbrugger, on "A new device for detecting hidden diseases within the human chest by percussion to the thorax." Of Lettson, the founder with Fothergill of the Medical Society of London, Dr. Lakin said that he was a man not greatly learned as learning counted in those times, but he was the impersonation of that valuable quality in a physician, common sense; and he had a heart of gold.

One hundred years ago George Owen Rees (1813-89) described the occurrence of hyperglycaemia in diabetes ("On Diabetic Blood," *Guy's Hospital Reports*, 1838). Though Matthew Dobson of Liverpool (1776) and the Italian chemist Ambrosiani (1835) had previously noted the presence of sugar in diabetic blood, its existence was doubted or ignored until Rees's demonstration. The first medical officer to Pentonville Prison, and lecturer on materia medica and physician at Guy's, Rees for many years was intimately associated with Alfred Swaine Taylor in some of the most celebrated criminal trials of the day. There is a comically grotesque drawing of Rees in *The Times Report of the Trial of William Palmer* (1856), and his portrait by Sidney Buck hangs in the Royal College of Physicians of London.

FORLANINI INSTITUTE: SCHOLARSHIP

The Privy Council announces that in connexion with the Carlo Forlanini Health Institute of Rome, a clinic for diseases of the respiratory system and tuberculosis, which organizes annually (from January to April) courses of training in phthisiology for foreign medical practitioners, the National Fascist Institute for Social Welfare offers to British medical practitioners:

1. A scholarship consisting of exemption from fees for registration and attendance at the course, free board and lodging at the Institute, and other facilities, including special railway facilities.
2. Three nominations entitling the holders to exemption from fees for registration and attendance at the training course, and other facilities, including special railway facilities.

Candidates must be qualified medical practitioners of at least three years' standing who have rendered effective service in specialized medical clinics or sanatoria or other scientific institutions for the treatment of tuberculosis. Any publications and attendance at other courses specializing in phthisiology can be considered as claims for preference.

With the concurrence of the Privy Council the British Medical Association has undertaken to receive applications from medical practitioners, who should communicate with the Secretary of the Association at B.M.A. House, Tavistock Square, London, W.C.1. not later than November 1, 1938, giving details of age, qualifications, and experience.

OPENING OF THE NEW SESSION GUY'S HOSPITAL

SIR HENRY DALE ON THE FUTURE OF MEDICINE

The annual prize distribution and opening address at Guy's Hospital Medical and Dental Schools took place on October 14, and was presided over by Viscount Nuffield, treasurer of the hospital.

Sir Henry Dale, after distributing the awards to the medalists and prizemen, gave an address on "The Future of Medicine." He began with a few remarks about research, which, he said, had been his own job in life ever since qualification. There was one particular direction in which it seemed to him that the need for research ought to make a special claim on the men qualifying for medicine in this country and in other parts of the Empire. A vast area of the tropical regions of the world lay under British rule, and it could properly be urged that British medicine had a special responsibility with regard to the diseases which still continued in those regions to take a terrible toll of life and health. Here if anywhere in the medical field many nuggets of discovery still lay relatively near the surface, to be won by trained observation, in alliance with some of the courage, enterprise, and resourcefulness which took British explorers into those regions in times before our own.

Revolutionary Changes in Medicine

Coming to his main theme, Sir Henry Dale said that what he had chiefly in view was to attempt to form an idea of the nature and scope of some of the changes to be expected in the medicine which it would be the privilege of those he was addressing to apply. It seemed certain that the future would show an acceleration of the change, already in progress, by which the activities of the individual practitioner in preventive medicine were supplemented, supported, and to some extent directed by the organized use of medical knowledge on behalf of the community. The conception of preventive medicine itself would widen, with a growing recognition that the ultimate aim of medicine was not merely to relieve, to cure, or to prevent diseases which could be recognized and labelled, but to define and then to obtain, so far as insistence could do it, the conditions for a full and healthy development, and for continued health, for every member of the community.

This was a time of exciting and even revolutionary change and progress in which to enter medicine. The beginnings of the change were to be found some sixty or seventy years ago in the extraordinary outburst of activity in what were now called the medical sciences, such as bacteriology and physiology. Owing to this renaissance it would be found that medical knowledge had advanced and practice changed with it more in the past few decades than in several centuries preceding them. As an example he mentioned the tragedy of deaths from diphtheria at a time, in his own early experience, when the suspicion of faulty drains represented the highest flight of medical speculation concerning the aetiology of the disease. Nowadays, to take the Province of Ontario as an instance, the immunization of school children with toxoid had become so well established that a position was in sight in which diphtheria would have ceased to count as a threat to the child life of a progressive community. Was he wrong in foreseeing that an important part of the duty of medical men of the future would be to educate themselves and the public opinion which looked to them for guidance so as to ensure that the benefits of such saving knowledge were secured for those whose health would be in their care?

Again, in his student days a case of diabetes mellitus in the wards was viewed with despair by the physician. The discovery of insulin had changed that picture, but it had done much more than transform the treatment of diabetes: it had given an enormous impetus to researches

on hormones in general. During the last twenty years active hormones had been obtained from the parathyroid glands, from the suprarenal cortex, from the different gonads, and, a whole series of them, from the pituitary anterior lobe. From liver and stomach mucosa materials had been extracted the administration of which restored to the victim of pernicious anaemia the factors missing from his blood-forming system. Insulin had been crystallized, thyroxine had been prepared by complete synthesis, while several of the sex hormones and that of the suprarenal cortex had been obtained as pure crystalline substances, structurally identified, and even prepared artificially by partial synthesis from different sterols. Twenty years ago it was held not to be certain that any of these substances had a real existence.

Further New Resources in Treatment

Recent progress in dietetics told a similar story. At the beginning of the century people talked about proteins, fats, and carbohydrates, and had some knowledge of the energy requirements of the body; but ignorance of qualitative dietetics was a reproach to medical science at that time, and medical advice on diet proved a fair target for the layman's humour. The change in recent years had been almost incredibly rapid. Twenty years ago it was possible to think of accessory factors as intangible traces of substances which might never be accessible to exact chemical study. Yet seven or more vitamins had now been separated in pure form, structurally identified, and prepared artificially by synthesis; and there were others, he believed, in near prospect.

All this illustrated the way in which research was providing new conceptions of aetiology and new resources for treatment based directly upon it. In his own student days one of his strongest impressions was the attitude of cynical scepticism then prevailing concerning the value of medicinal treatment. It was depressing to him at that time how seldom a prescription appeared to be written with any clear confidence in a real effect on the disease.

"Who would have ventured then to predict the day when it would become possible, by the use of natural remedies, to make a whole population resistant to diphtheria infection, or practically to abolish rickets in the children of a modern city, or to restore hormonal defects in the diabetic and the sufferer from pernicious anaemia, so as to enable them to live almost normal lives?"

The same kind of change was perceptible in the therapeutic use of artificial chemicals and substances unnatural to the body. Synthetic chemistry had done real service to medicine. He instanced prontosil and its active moiety sulphanilamide, and the brilliant new prospect thus opened of the successful treatment of conditions due to infections by streptococci, such as puerperal fever and erysipelas. Synthetic substances were coming to hand which dealt radically with the causes of disease, and not merely modified or moderated the resulting symptoms. This was a change only now becoming effective, and seemed to him certain to continue and to be more rapid in the future.

Sir Henry Dale concluded by affirming his faith that, with the disappearance of the earlier separation and critical rivalry between experimental research in laboratories on the one hand and empirical observation at the bedside on the other, and with the formation of a common front of advance in medical science, medicine would move towards the ideal of the creation and maintenance of the conditions of health, and not limit itself to the recognition and treatment of acute or obvious failures and anomalies.

"Sooner or later, in any case, the new weapons of science will come to your hands, and one of the most important developments which I hope that the future will see is the intelligent and enterprising use of the new knowledge by the man in ordinary practice, enabling him to retrieve, from the limbo of 'imaginary' ailments, many hormonal and dietary deficiencies, many chronic reactions to latent infection, and

many partial failures in factors of normal function yet unrecognized which future researches may reveal. If we can look forward to the time when the man in ordinary practice will be able to recognize, anticipate, and deal with the causes of vague and chronic ailments which bear no diagnostic labels and seldom reach the hospitals, then, indeed, I believe that the future of medicine is bright with the hope of better service to the health of mankind."

HAEMOLYTIC ANAEMIAS OF CHILDHOOD

LECTURE BY PROFESSOR L. G. PARSONS

The Schorstein Memorial Lecture was delivered on October 13 at the London Hospital Medical College by Professor Leonard G. Parsons. Dr. Robert Hutchison, P.R.C.P., presided. The lecturer took for his subject the haemolytic anaemias of childhood, on the basis of a study by himself and his colleagues of 120 cases.

It used to be stated, said Professor Parsons, that anaemias were divisible into primary and secondary. Such a classification existed for many years but was now obsolete, and it was clear that anaemia was much more a symptom than a disease. The attachment of personal names, whether Teutonic, or American, or even British, like those of Addison or Wits, to certain clinical syndromes was quite futile as a contribution to the classification of anaemias, however excusable on the ground of hero-worship.

Most classifications of anaemias divided them into those due to deficiency or inability to utilize material for the manufacture of red cells and those due to loss of blood; but it was possible for a given anaemia to fall under both heads. Continued loss of blood, as in excessive menstruation or bleeding piles, might lead to a depletion of the iron stores of the body, and unless this was made up by increased intake of iron iron-deficiency anaemia occurred.

The red cell passed through a series of changes from the reticulum in the marrow to the erythrocyte in the blood stream, and in the absence of certain materials in the bone-marrow a particular change might not take place. In the haemolytic group of anaemias reticulocytes formed a conspicuous feature of the blood film, not infrequently accompanied by an increase in the granular cells. The conception of the essential unity of the red cell in the blood stream and its precursors in the haematopoietic "factory" had been one of the great features of the haematological renaissance of the last decade. The word "haemolytic" was now so firmly engrafted in medical literature that it must be accepted, but in so doing Professor Parsons said that he was adopting the reprehensible practice of holding a candle to the devil.

Erythronic Response to Injury

The character of erythronic response was conditioned by (1) the part of the erythron most affected (meaning by erythron the tissue made up of circulating red blood cells and the cells from which they arose), as, for example, periphery or marrow; (2) the severity of the injury and the length of time for which it had lasted; (3) abnormalities of the erythron; and (4) abnormalities of the serum. As a result of the different varieties of erythronic response various forms of haemolytic anaemia were seen, of which he gave a list. Abnormalities of the erythron might give rise to acholuric jaundice, sicklaemia, Cooley's anaemia, or haemoglobinaemia. Abnormalities of the serum included haemolysins, alteration in blood lipoids, toxins of infection, and allergic states.

In discussing erythroblastosis the lecturer gave reasons which made him regard this condition as haemolytic. Erythroblasts occurred in foetal blood, and were therefore apt to occur in the newborn child. They were often found, indeed, in a normal full-term child, and sometimes

to an extent which was almost pathological. Sepsis or syphilis might produce a picture identical with icterus gravis at any time during the first fortnight of life. The degree of erythroblastosis probably depended upon the degree of development of the extramedullary centres, and was in his opinion a response to haemolysis, and not a primary pathological condition.

Von Jaksch's Anaemia

Professor Parsons believed that many children said to be suffering from von Jaksch's anaemia were really victims of haemolytic anaemia. This condition, which usually occurred in a child under 3 years of age, was insidious in onset and the prognosis was good. There was usually at some time during the illness a leucocytosis. Von Jaksch did not give a very clear account of this anaemia. The syndrome occurred during the "deficiency age period" of a child's life—that is to say, the period when infantile scurvy or rickets was likely to occur. The von Jaksch picture might be found during the course of icterus gravis and in young children suffering from sub-acute haemolytic anaemia. He believed von Jaksch's anaemia—which was not an anaemia at all in the sense of a clinical entity—presented really the blood picture occurring in erythroblastic anaemia, probably only during the deficiency disease age period. He quoted three cases of supposed von Jaksch's anaemia. In one the duration was four months, and it was significant that a cousin of the child had acholuric jaundice. The second case was of three weeks' duration, and this had been said to be, by another observer, an undifferentiated medullary reticulosis. In both these cases there was erythrophagocytosis. The third case was of two years' duration, with fibril formation, and was ascribed to aplastic marrow.

Sickle-cell and Cooley's Anaemias

Passing to more chronic forms, Professor Parsons discussed certain differences between acholuric jaundice and ordinary haemolytic anaemia. Sicklaemia occurred mainly in negroes; here many of the red cells were sickle- or crescent-shaped. The haemolytic nature of sickle-cell anaemia could not be denied. The bone changes in this condition were very marked and more frequent than in acholuric jaundice. Another interesting point in sickle-cell anaemia was that after puberty the spleen seemed to atrophy.

Cooley had described a form of anaemia which he called erythroblastic. It was almost entirely limited to children of Syrian, Italian, or Greek stock. When the disease was fully developed the changes in the bones of the skull and face produced a mongoloid appearance. The spleen was generally enlarged, and often the liver and lymph glands. In the long bones the cortex was thin and transparent and the medulla showed reticulation. He mentioned a case of a boy aged 4 shown by Smallwood and himself to the British Paediatric Association which had affinities to both sickle-cell and Cooley's anaemias. There were abnormal cells in the blood and characteristic bone changes. The parents denied any possible negro strain in the ancestry, but returned next day rather shamefacedly confessing that one of the child's grandparents was Scotch! An anthropologist who was consulted stated that the child was negroid in feature. A striking part of the case was the great increase of erythroblasts in the blood after splenectomy. The boy had never been jaundiced, although he was slightly yellow in colour. The case was probably one of chronic haemolytic anaemia forming a connecting link between sickle-cell and Cooley's anaemias and other chronic haemolytic anaemias.

The varieties of haemolytic anaemia and certain other allied conditions owed their clinical characters to the permutations and combinations of the response to an injury. Fresh combinations might be expected to occur from time to time, and it was improper to regard the different forms observed by different authors as hard-and-fast types.

INFANTILE PARALYSIS AND CEREBRAL DIPLEGIA CLINIC AT CARSHALTON

The following report has been received for publication from the London County Council.

Anterior poliomyelitis, commonly known as infantile paralysis, is a disease which causes permanent paralysis of one or more limbs in a large proportion of those affected. Of the physically defective children admitted to the special or hospital schools of the London County Council approximately sixty each year owe their disability to this disease. The arrival in England of Miss Elizabeth Kenny, who had done much work on infantile paralysis and allied crippling diseases in Australia, was therefore of great interest. The Council decided that her claims to be able to prevent permanent paralysis and to effect great improvement in these diseases should receive every opportunity for demonstration, and that the fullest scientific investigation should be made. With this end in view the Council agreed to afford Miss Kenny the necessary facilities, and an experimental unit was started at Queen Mary's Hospital for Children, Carshalton. In order to ensure proper assessment of the value of the treatment the Medical Officer of Health invited several prominent specialists in association with the medical staff of the hospital to observe and investigate it; their opinions are given in the subjoined report. Before leaving England in August, 1938, Miss Kenny wrote the following letter to the Clerk of the Council:

August 12, 1938.

DEAR SIR,—On the eve of my departure for Australia I wish to place on record my appreciation of the action of the London County Council in affording me the necessary facilities to demonstrate my method of the treatment of infantile paralysis and spastic paralysis. Prior to my arrival in England no such trial had been arranged. I also appreciate very much the honour of the association in the work of the medical committee arranged by your Council. Also the Council's employees who were associated with me at Queen Mary's Hospital. My stay in this institution shall ever remain as one of the most pleasant experiences of my life.

Again thanking you very much.—Your sincerely,

(Signed) E. KENNY.

REPORT ON THE KENNY METHOD OF TREATMENT

The period of one year has expired since Miss Kenny, with the Council's sanction, began the demonstration of her methods of care and treatment of poliomyelitis and of cerebral spastic paralysis. The work started on July 13, 1937. A ward was evacuated, and was equipped as a clinic with the baths and other apparatus used by Miss Kenny and described in detail by her in her book, *Infantile Paralysis and Cerebral Diplegia* (Angus and Robertson, Sydney, Australia, 1937). Two adjoining wards (twenty-eight beds) and, later, a third ward (eighteen beds) accommodated the in-patients. There were also a small number of out-patients who have attended daily, every other day, or at such periods as were prescribed. The wards were staffed by members of the regular hospital nursing staff, whose numbers were somewhat increased beyond the hospital standard on account of the intensive care required day and night by Miss Kenny.

Miss Kenny brought with her two of her Australian trainees, who have assisted her continuously through the whole period, and to complete the staffing five of the whole-time trained massage staff (with the part-time services of the massage superintendent) were appointed to learn the details of Miss Kenny's methods and work under her direction. From November to April Miss Kenny herself had to return to Australia, and during this period she delegated the supervision of the treatment to Dr. F. H. Mills, M.B., B.S., Sydney, who is familiar with the system, and to her senior trainee (Miss Grant). In this way continuity was preserved. From the hospital side the whole unit was supervised by Mr. G. M. Gray, F.R.C.S., one of the Council's senior resident

assistant medical officers, who has devoted his whole time to this work and to the careful observation of every one of the patients, as well as the detail of the treatment given.

In the first place the agreement with Miss Kenny was that her work should be demonstrated for three months, but at the end of that time it became obvious that this period was too short for any reliable opinion to be formed as to the results of her treatment and, accordingly, it was later agreed to extend the period to twelve months.

In view of the interest which has been aroused and the manifest importance of the whole matter the Medical Officer of Health of the Council invited the assistance of orthopaedic surgeons and neurologists to form an honorary advisory committee to watch the treatment carried on and to be associated with the Council's officers (Dr. H. O. West, M.D., F.R.C.P., D.P.H., medical superintendent of Queen Mary's Hospital, and Mr. G. M. Gray, M.A., M.B., Ch.B., F.R.C.S.Ed., F.R.C.S.Eng.) and the consulting orthopaedic surgeon to the hospital (Mr. C. Lambrinudi, F.R.C.S.) in their conclusions. There were accordingly appointed: Mr. H. A. T. Fairbank, D.S.O., O.B.E., M.S., F.R.C.S., Mr. R. C. Elmslie, O.B.E., M.S., F.R.C.S., Mr. E. I. Lloyd, M.A., M.B., Ch.B., F.R.C.S., Dr. Macdonald Critchley, M.D., F.R.C.P.

In accordance with Miss Kenny's request for the admission to Queen Mary's Hospital of cases of poliomyelitis in the early stage of the disease all such cases coming under the Council's care were admitted to this unit. In addition a number of cases of residual paralysis in poliomyelitis selected by Miss Kenny were transferred to her care, and also a few cases of cerebral spastic paralysis which she considered were suitable for the demonstration. In all, sixty-three patients have been treated, as follows:

Poliomyelitis:

(a) Recent (treatment commencing less than 8 weeks from onset)	34
(b) Later (treatment commencing over 8 weeks and less than 12 months from onset)	12
(c) Residual (treatment commencing over 12 months from onset)	9
	55

Cerebral spastic paralysis

8
63

In general Miss Kenny's treatment has not been interrupted or interfered with in any case except as the result of incidents (such as infectious diseases) which could not be controlled. Even in cases in which infectious diseases occurred interference was avoided as far as possible by one of the trainees going daily to the fever hospital, with the kind co-operation of the medical superintendent (Dr. J. S. Anderson, Grove Hospital).

Miss Kenny claimed in her book that she has obtained complete recovery in all recent cases of poliomyelitis which she has personally treated from the commencement.

"*Infantile Paralysis*.—All recent cases treated at the clinic [Townsville] have been totally and permanently cured. . . . It must be acknowledged that the number of recent cases of infantile paralysis at that time was very few—in fact, four only. During the last two years this number has been increased to twelve, with the same happy results" (p. xxi—author's preface).

Herein lies the importance of the admission of early cases already alluded to. If we correctly understand from this that Miss Kenny claims to be able to cure poliomyelitis completely, then we are of the opinion, as the result of our observations during the past year, that such a claim is in no way substantiated.

Miss Kenny's Five Principles

There remain, therefore, the questions whether Miss Kenny's methods are better than customary methods, whether they yield better or more rapid results, and

whether they should be recommended for general adoption. These methods are enumerated as follows (*ibid.*, p. 3): (1) maintenance of a bright mental outlook; (2) maintenance of impulse; (3) hydrotherapy and remedial exercises; (4) maintenance of circulation; (5) avoidance of the generally accepted methods of immobilization. These may now be considered seriatim.

1. *Maintenance of a Bright Mental Outlook.*—We certainly agree that an optimistic outlook should be adopted both by the patient and by those under whose care he is placed; but in a disease such as poliomyelitis this must be tempered by the judgment of clinical knowledge, otherwise it is liable to become mere deception.

2. *Maintenance of Impulse.*—We understand Miss Kenny to mean by this that the patient must be helped to make the mental effort to carry out a movement even when the muscles are so completely paralysed that no movement and no tightening of them can be perceived. We do not agree that any mental effort to produce muscular contraction can be felt by an attendant's hand unless contraction actually occurs. Miss Kenny's "impulse" is presumably a minimal contraction of the muscle, which may be so slight as to require experience in its detection. On the other hand we agree that the voluntary contraction of muscles that have been paralysed or weakened should be encouraged by every possible means. This is, of course, in accordance with generally accepted views.

3. *Hydrotherapy and Remedial Exercises.*—Miss Kenny's method of hydrotherapy is carried out in individual slipper baths or in a special "arm" bath. A warm bath is used, with a hot and cold douche as a method of stimulation, and in it the limbs are exercised. The principle of under-water exercises is not a new one, but in hospital practice it is more often carried out in communal baths. The use of alternating hot and cold douches appeals to us as useful. Miss Kenny sets out the merits of hydrotherapy: (i) the circulation in the limbs and skeletal muscles is improved; (ii) their nutrition is maintained; (iii) the buoyancy of the saline water assists weak movements; and (iv) hydrotherapy improves the mental outlook (*ibid.*, p. 7). With this view we agree, and we think Miss Kenny's method is of value, but we cannot altogether accept her criticisms of the "communal bathing pool," which are as follows: (i) the proximity of other patients causes distraction; (ii) the effort to keep afloat causes lessening of mental concentration; (iii) it is impossible to obtain the same degree of co-operation between the patient and attendant that the individual bath affords; (iv) a newly acquired movement may not be perceived as soon as it may be by the method of the individual baths, and through this oversight, may be overtaxed and so weakened; and (v) that hygiene is lacking (*ibid.*, p. 7). All these objections can be overcome. Large baths are no doubt to some extent unhygienic, but their use is limited to patients in hospital, and frequent changing of the water and simple hygienic measures are universally practised. Actually we think there are certain objections to the small individual slipper baths: there is not room for certain movements—for example, abduction of the lower limbs—and the use of the principle of buoyancy is limited.

We must now refer to the important question of when remedial exercises (or muscle re-education) are to begin. Miss Kenny strenuously advocates muscle re-education as early as possible in the course of the disease, and is not unwilling to practise this even before the cessation of pain. Her method of re-education consists essentially of passive movements which the child is invited to assist, if possible, by voluntary contraction of the appropriate muscles. It might be expected that such early movements would eliminate the incidence of stiffness so often observed when immobilization by splinting has been unduly prolonged. But we have seen stiffness arising quite early when no splint has been used. It does seem that real progress in passive mobility is only made when the pain has disappeared. Miss Kenny claims that her method of hydrotherapy, fomentations, and passive movements helps to get rid of pain. Our observations upon this point are inconclusive, because the duration of pain in individual cases varies greatly.

4. *Maintenance of Circulation.*—Miss Kenny attaches great importance to this, and we think rightly so. Though it is a matter which is usually attended to with care in individual cases at home, it has to be admitted that it should receive more attention in hospital practice. Among the ill effects Miss Kenny ascribes to failure to maintain a good circulation are the following:

(i) *Loss of Muscle Tone.*—This is well known to the massage profession, whose members find that they cannot get the muscles active until the limb has been warmed up.

(ii) *Wasting.*—This depends mostly on the extent of the damage to the nerve cells, and the influence of peripheral circulatory factors is slight. In the cases under review there certainly is wasting, but there is no doubt that the texture of the skin and subcutaneous tissues is good.

(iii) *Chilblains.*—These also have not occurred, but we should say (a) that chilblains ought not to occur in such children who are in-patients in a hospital, and (b) that they are late manifestations and are not usual in the first year.

5. *Avoidance of the Generally Accepted Methods of Immobilization.*—In this principle Miss Kenny appears to differ fundamentally from what is described as the "orthodox" view. Dr. Mills, describing her method (*British Medical Journal*, 1938, 1, 168), summarizes "orthodox" methods of treatment:

"The accepted or orthodox methods of treatment may be summarized as follows: (a) rest and immobilization of the affected limbs until the stage of pain or irritation is past; (b) maintenance of affected muscles in a position of relaxation; (c) avoidance of contractures and deformities by light retentive apparatus; (d) massage and active and passive movements. Treatment along these lines is based upon the theory that the pain in the limbs is of central or meningeal origin. . . . In opposition to this accepted theory the view is taken that the pain in the extremities is almost completely vascular in origin."

While this summary may be generally accepted it is necessary to point out that "orthodoxy" is not a precise term. Indeed, it is well known that orthopaedic surgeons differ widely in the practical application of the principles of splinting and immobilization; so that when "immobilization" is spoken of and condemned by Miss Kenny as if it were the habit of all orthopaedic surgeons to place children on a retentive frame or in splints without any other treatment for an indefinite period of time, even extending to months, and the production of deformities is ascribed to the splints themselves, her view is inaccurate. While we should agree that "immobilization" may be practised over-long, we are opposed to Miss Kenny's refusal to use any splint at all in the treatment of this disease. All retentive splintage must be employed intelligently and with discretion as a means to an end and not merely as an end in itself. Miss Kenny claims that the initial period of rest and immobilization is unnecessary and adheres to the "theory of natural posture in correct alignment without immobilization," meaning thereby that the body and limbs should be kept in their natural position in the intervals between exercises. This she aims at maintaining by the constant attention of the trainees or nurses and by means of pads and slings and boards at the end of the bed to prevent "footdrop." She thus uses "position" but will not adopt the use of splints to maintain it.

Apart from some degree of contracture of the tendo Achillis in a few cases that was overcome later, we have seen the development of no contractures while the patients were recumbent and well supervised, nor have we found evidence that her refusal to put the paralysed muscles in the position of relaxation has caused delay in the initial return of power. We think, therefore, that it must be admitted that Miss Kenny's method of keeping limbs in a neutral position without splints when in bed is not harmful in the early stages of the disease, and in fact has this to commend it—that it spares the children the irksomeness of splints at that stage. On the other hand we are as definitely of the opinion that, when a muscle is recovering, splints are often useful in preventing over-fatigue and deformity. It follows from this that we think Miss Kenny's prejudice against splints and appliances leads her to keep the children recumbent unnecessarily long, when the judicious use of an appliance might enable them to get about earlier with no harm to the muscles and joints and even with benefit to the muscles and to the child generally.

It is certainly vital to Miss Kenny's system that there should be constant supervision. Such intensive care seems only possible in an institution specially equipped and staffed for the purpose.

Exercises and Other Procedures

With these five "principles" in view Miss Kenny uses "exercises and other procedures for the restoration of functional power to apparently paralysed muscles." It

is not, we think, necessary to describe in detail her methods of "muscle re-education." They are simple, and can be carried out by trainees who have not been as fully instructed in anatomy and physiology as are members of the massage profession. We have seen nothing to suggest that Miss Kenny has designed methods superior to those used by the massage profession. In fact, we consider it is legitimate criticism of her method that it does not include a number of useful measures practised, certainly in this country, by experienced masseuses. As we have already observed, Miss Kenny's system involves that such muscle re-education should be begun in the early stages and should be continued throughout the treatment, and she claims on its behalf that it maintains the dormant normal impulses which she believes wither under immobilization methods and may die beyond the hope of resuscitation. Careful graduation of exercise as practised by her avoids over-fatigue, and in this she follows well-established practice. Treatment by early movements, it must be noticed, is being practised in several other centres abroad. We have seen no evidence that the early movements in the cases we have observed have been harmful, but neither have we reason to think that they have specific value in determining the degree of restoration of useful function. This method has perhaps encouraging psychological effects which may be beneficial. It is noticeable that in some of the severe cases treated from an early stage all the efforts of Miss Kenny and her staff have failed to bring back any movement in the paralysed muscles.

Twelve months is too short a period in which to assess finally the question of residual paralysis. In our view Miss Kenny has not really faced this issue. If we understand her aright, she believes that, under her system, in two—or perhaps three—years' time her patients will not require artificial aids, and, having sufficient useful function, will not require any surgical supervision or after-care. We wish we could believe this to be true. It is of course well known that some patients with poliomyelitis recover to a considerable degree under any system of treatment and that they may continue slowly to improve for a long time, but so far as our twelve months' observation of this very interesting experimental period has gone we have seen nothing whatever to justify Miss Kenny's belief. We have been especially interested in her opinion, expressed late in the year, that she is satisfied if she can get partial recoveries—for example, in an arm case she aims at a "good forearm," and in a leg case at "good gluteal muscles," leaving stabilizing operations to the surgeon. This differs little from the accepted view in this country. In this she seems to abandon her claim to effect a complete cure.

It is necessary, we think, to refer only briefly to Miss Kenny's treatment of cases of cerebral spastic paralysis. By her extreme attention to detail, incessant and intensive application, coupled with most admirable patience and optimistic enthusiasm, Miss Kenny has achieved some amelioration in the cases under treatment. But there is nothing original in the principles of her treatment, and it is very doubtful whether any of the more severely affected patients treated can ever become self-supporting. In our experience of these cases improvement of some sort under any intensive system of training or treatment often occurs. No doubt this is encouraging to the relatives of these patients, but relapses are not infrequent following the cessation of treatment.

General Observations

We may conclude this report by some general observations. We have indicated our view that this system is not the last word in the treatment of poliomyelitis. (We disagree with Dr. Mills's enthusiastic support, and feel bound to record our opinion that it was unfortunate that his article on the subject (*loc. cit.*) was published during the course of this investigation.) At the same time no

one can be complacent about this distressing disease, and we should be ready to adopt any method of proved value and incorporate it in "orthodox" treatment, so called: Miss Kenny herself has consistently expressed her desire to be of service through regular medical channels. We should therefore have no difficulty in recommending—certainly for an extended period—the continuation of Miss Kenny's system of hydrotherapy in the poliomyelitis unit of this hospital. Having expressed the opinion that this is of value, it would seem foolish not to use the apparatus which has been installed. We see no difficulty and no inconsistency in incorporating this part of Miss Kenny's system, for instance, in a major scheme of treatment which would include splintage where this is thought advisable.

We are in no doubt as to the value of the segregation of cases of poliomyelitis in large special units. This was originally suggested to the Council by Mr. Elmslie and resulted in a unit at Queen Mary's Hospital, with a preliminary period at the Western Fever Hospital because of the supposed risk of infection. The present series of cases seems to have shown that no disadvantage has followed the transference of cases to Carshalton at an earlier stage than hitherto, and we should be glad to see the intensive treatment which has resulted from Miss Kenny's visit continued. Though it is incapable of proof we believe there is no appreciable risk of infection—an opinion which agrees with the generally accepted views on the subject.

Certainly we hope that arrangements will be made for the continued observation of these particular cases for reasons already indicated.

Summary

We should therefore sum up our main conclusions as follows:

1. We have seen no reason to admit Miss Kenny's claim that complete cure can be promised in any group of cases of poliomyelitis.

2. We consider that the use of hydrotherapy in the form of hot and cold douches as practised by Miss Kenny is of value.

3. We consider that very early attempts to initiate voluntary movements and also early and frequent passive movements are harmless but of unproved value. We think, however, it is a legitimate criticism of her method generally that it does not include a number of useful measures practised, certainly in this country, by experienced members of the massage profession.

4. We agree with Miss Kenny that under certain conditions, which we have specified, splints can be dispensed with in the treatment of the early stages of the disease. We do not approve, however, of her entire abolition of splints and surgical appliances in treatment. We consider that they are often valuable and sometimes essential parts of treatment, but, on the other hand, we are equally sure that the mechanical methods which she employs in substitution for splints are inadequate. We would add, however, that we disagree with the long periods of continuous mechanical immobilization which are sometimes imposed.

5. We consider that Miss Kenny has not really faced the issue of residual paralysis, for which we believe surgical appliances or surgical methods such as stabilizing operations offer the only eventual hope of amelioration.

6. Some improvement appears to have been achieved in the cases of cerebral spastic paralysis treated, but Miss Kenny's system demonstrates no original principles.

MOTOR CARS FOR 1939

THE EARL'S COURT EXHIBITION*

[FROM OUR MOTORING CORRESPONDENT]

Reference was made last week to the increasing popularity of four-cylinder engines for cars up to 12 or 14 h.p. The annual analysis published by the *Autocar*, however, taking all the models together, shows that vehicles with six-cylinder power units are still in the ascendant, the proportion of such models to the total having advanced from 45.5 to 48.2 per cent.; 35.3 per cent. of the new cars have four-cylinder engines, the rise in this case being from 32.5 per cent. The analysis also reveals that cars with four-speed gears are far and away the most popular, the proportion of four-speed gears being 64.1 per cent. as against only 29.4 per cent. for three-speed gears.

The cars to be seen at the exhibition range in taxable h.p. rating from 8 to 51, and in price, taking those with saloon bodywork as a basis, from £120 to about £3,000. The needs of medical men are so varied that no hard-and-fast rules can be laid down as to the most suitable vehicles for their use. Where low travelling costs are important any of the Tens can be relied upon not only to perform satisfactorily but to have a good appearance—a point of some importance to medical men. The majority, however, will probably make their choice among the Twelves and Fourteens.

Alvis, Armstrong-Siddeley, and Austin

The 12/70 four-cylinder Alvis with a saloon body is listed at £435, and as a drop-head coupé at £445. Only slight mechanical modifications have been found necessary, but the bodywork has been re-designed to give more leg- and head-room and at the same time wider seating. There are two new Armstrong-Siddeley models—a Sixteen made in two styles of saloon body, priced at £380, and a Twenty—for both of which a new slogan, "balanced drive," has been coined to draw attention to the harmonizing of the chassis, suspension, and bodywork to provide "restful motoring." Other features of the Sixteen include a new chassis frame and a fluted steel floor, which prevents any engine fumes passing into the interior of the car. Only vehicles with six-cylinder engines are manufactured by the Armstrong-Siddeley concern, which is continuing the Fourteen and Seventeen saloons with only slight modifications, at £335 and £475 respectively.

The Austin company has as usual a wide range, comprising no fewer than twenty-seven different models of cars and seven distinct chassis types—the Seven, Big Seven, Ten, Twelve, Fourteen, Eighteen, and Twenty-eight, the last-named being an entirely new model replacing the former 20-h.p. Austin. The first four have four-cylinder engines, the other three being "sixes." Although there are no radical departures in the latest models, a great number of detail improvements have been made. Thus, the new design of engine with an aluminium cylinder head, last year used only on the Fourteen, is now applied to the Ten, Twelve, and Eighteen models. Providing a higher compression ratio, this innovation, in combination with larger inlet valves on the Ten and Twelve, is claimed to ensure a higher power output with at the same time a reduced fuel consumption. Among other modifications which may be referred to are the higher and wider doors on the Twelve and Fourteen vehicles, the hinged front seat squabs on the Tens, to allow greater mounting and dismounting space, and sturdier back axles to withstand the increased engine power on the seven and three next following types. An important feature of the Austin 1939 programme is a reduction in prices of from £5 to £15; as one example it may be mentioned that the Ten sunshine-roof saloon is now priced at £185, or £10 less than last year.

B.S.A., Citroën, Chrysler, and Daimler

A car which may appeal to the younger medical men is the 10-h.p. B.S.A. Scout, the range of which now includes

an attractive two-door saloon listed at £196. The chassis, the only one of British construction embodying a front-wheel drive, is provided with a newly designed four-cylinder engine. Among the special features is the location of the change-speed lever just below the centre of the instrument board with the pistol-grip hand-brake lever at its side, so that both these controls are removed from the floor boards. The Citroën company has added two new models to its range of cars—namely, popular saloons on both the Twelve and Light Fifteen chassis at £198 and £208 respectively. Only slight modifications have been made in the Citroën vehicles, which are noteworthy for their independent front-wheel suspension and drive.

For the new season the Chrysler concern has a series of six models ranging in power from 20 to 34 h.p., and in price from £335 to £975. Among the new features are independent front-wheel suspension, an improved form of overdrive in connexion with the change-speed gear, which latter in certain models is controlled by a lever on the steering column, and a new "traffic lights" speedometer dial, which shows a small green light up to 30 m.p.h., amber from 30 to 50 m.p.h., and red at higher speeds. In the latest Daimler Fifteen model the power of the engine has been increased to 18 h.p. to denote which, and also in relation to its progenitor, the name has been altered to the Daimler 2½-litre "15." Except as regards the power unit, the chassis, which has independent front-wheel suspension and, of course, the Daimler fluid flywheel and self-changing gearbox, has not been altered. There is, however, in addition to the saloon, which sells at £485, a new four-door drop-head cabriolet.

Dodge, Fiat, Ford, and Frazer Nash

An interesting car of American design and construction is the Dodge, of which 20-, 24-, and 26-h.p. six-cylinder and 34-h.p. straight-eight models are available. Like the Chryslers, with which they are closely related, the Dodge innovations include independent front-wheel suspension and an improved overdrive to which the name "dual power" has been given, this being designed to come into operation automatically on either top or second gear at speeds as low as 22 m.p.h. A five-seater saloon is available with either a 20- or a 24-h.p. engine at £365. Among the Fiat cars, which are of Italian design, chief interest centres in a new Twelve, which is supplied only with a saloon body at £227; there is, however, a special foursome drop-head coupé body on the 10/12-h.p. chassis at £265.

Although not shown at Earl's Court, it may be mentioned that the Ford Ten car is in future to be known in its improved form as the Ford Prefect. Outwardly it resembles the V-eight model scaled down, with a flat-topped bonnet and streamlined front. The new prices range from £145 for the two-door saloon to £152 10s. for the four-door model. The A.F.N. company has three types of chassis—12-h.p., 14-h.p., and 16-h.p.—bearing the Frazer Nash name, and a series of four six-cylinder models ranging in power from 13 to 25 h.p., known as the Frazer Nash-B.M.W., the name indicating a combination of German chassis with various British modifications. The prices range from £375 upwards, and the body types available include some attractively designed cabriolets and coupés.

Hillman, Humber, and Hudson

The popular 10-h.p. Hillman Minx has been reduced in price for the 1939 season, and, according to the makers' announcements, their latest productions, while remaining basically unchanged, embody no fewer than twenty-five new features, chief among which are the all-synchromesh four-speed gearbox, improved spring suspension, and more space in the front seat compartment. Three models with saloon bodies are available at £163, £166, and £175 respectively, together with an attractive foursome drop-head coupé at £210. A car which should appeal to medical men requiring a more roomy vehicle than the Minx is the Hillman Fourteen, with "evenkeel" independent front-wheel suspension and the synchromesh four-speed gearbox. Two models of saloon cars are available on this chassis—the Safety at £239 and the De Luxe at £255.

* Concluded from page 807.

Various detail improvements have been made in the Humber 16-h.p. and 21-h.p. Snipe cars: the saloons are now listed at £345 and £355. A new departure by the Humber company is the introduction of a Super Snipe car—a British endeavour to provide a big-engined vehicle to compete with American productions. The latest model possesses not only all the usual Humber features, such as the "evenkeel" independent front-wheel suspension, but is provided with a 27-h.p. engine, the "flexibility" of running of which is such that, except when starting, there is practically never any need to change down from the direct drive. It is claimed that a speed of 85 m.p.h. can be comfortably attained in the saloon, which is priced at £385.

Two six-cylinder models (17-h.p. and 22-h.p.) and a 29-h.p. "straight-eight" form the 1939 series of Hudson cars, all of which have undergone various changes in outward appearance. A new mechanical feature—the "auto-poise sway eliminator"—is said to make for greater riding comfort. The 17-h.p. and 22-h.p. saloons are offered at £312 and £360, there being also a convertible foursome coupé on the 22-h.p. chassis at £400.

Jowett, Lanchester, M.G., and Morris

The Jowett 8-h.p. and 10-h.p. cars, which continue as the only vehicles on the market with horizontal engines, and which are very popular with many country doctors, have undergone no radical alteration, but for the coming season embody numerous detail improvements. Despite this it has been found possible to reduce the prices slightly, the two-cylinder saloons being listed at £159 10s. for the standard and £169 10s. for the *de luxe* models, while in the 10-h.p. type there are three saloons at from £179 to £195. The Lanchester company is continuing to confine attention to three types of chassis—11-h.p. four-cylinder and two "sixes" of 14 and 20 h.p. respectively, although the latter is known as an "eighteen." The chief feature of these vehicles is that they all embody the Daimler fluid flywheel and pre-selective self-changing speed gear; various detail changes have been made, but otherwise these cars, which have an excellent reputation for reliability and smooth running, continue as last year. The 11-h.p. saloon is priced at £298 and the 14-h.p. Road-rider at £375. Among the cars appealing to young medical men are those bearing the name "M.G.," of which 10-h.p. and 12-h.p. four-cylinder models and 18-h.p. and 20-h.p. "sixes" are available in open tourer, saloon, and drop-head coupé form at prices ranging from £222 to £468; a noteworthy exhibit is a 10-h.p. "Midget" with Tickford folding-head four-seated bodywork at £269 10s.

The Morris cars continue to maintain their popularity. Although the range continues as before—namely, 8-h.p., 10-h.p., and 12-h.p. four-cylinder and 14-h.p. and 25-h.p. "sixes"—the Eight and Ten are entirely new models, the smaller one, indeed, having been kept back as a show surprise. The new car is bigger than the popular car it has displaced and shows a number of improvements, varying from a four-speed synchromesh gearbox to self-cancelling direction indicators. Four types of bodywork are being provided on the chassis—two open ones and two saloons, the latter ranging in price from £128 to £149. The Morris Ten has been reduced in price to £185 for the sunshine-roof saloon, and has also been re-designed, the all-steel saloon bodywork incorporating the chassis as an integral part. Among the points which will commend themselves to Morris car users are the four-speed synchromesh gearbox, the draughtless ventilation, the roomy passenger and luggage accommodation, and the full-width shelf below the instrument board. In the other three models only detail modifications have been found necessary.

Renault, Railton, and Rover

The Renault company is again showing examples of its 8.3-, 12.1-, and 17.9-h.p. four-cylinder and 29-h.p. "six" models. The smallest chassis has a special form of independent front-wheel springing, while on all four types the

rear suspension is by a single transverse spring in place of the usual pair of longitudinal springs. The Renault bodywork is known for its spaciousness, the larger vehicles being able to accommodate three persons on the front seat. Prices range from £140 for the 8.3-h.p. saloon to £295 for the 27-h.p. six-seater.

Included in the range of Railton cars is an attractive 10-h.p. chassis, two examples of which—a two-door three-seater saloon at £299 and a drop-head coupé body for three persons at the same price—are to be seen on the stand of Coachcraft Ltd. The chief new departure in the Rover series of cars—all of which retain an exclusive feature, that of a free-wheel-at-will device—is an entirely re-designed Fourteen six-cylinder model, which is now taxable at 15 h.p. The Rover range comprises 10- and 12-h.p. four-cylinder and 14-, 16-, and 20-h.p. "sixes" at prices ranging from £275 to £478. On each type of chassis the standard bodywork is of saloon type, but on the 10-h.p., 15-h.p., 16-h.p., and 20-h.p. chassis coupé bodies are also available.

Singer, S.S. Jaguar, Standard, and Sunbeam-Talbot

The Singer company is concentrating its energies on three types of four-cylinder cars—9-h.p., 10-h.p., and 12-h.p.—in which only minor modifications have been found necessary. Prices for saloons range from £149 10s. for the Bantam Nire to £249, there being also a special drop-head coupé body on the 12-h.p. chassis at £279. Another concern which is continuing its 1938 Jaguar models with only minor changes is S.S. Cars Ltd. Two "sixes" (20-h.p. and 25-h.p.) and 14-h.p. four-cylinder models are available, with saloon and drop-head coupé bodies constructed on attractive lines at prices ranging from £298 to £465.

The most striking feature of the Standard company's 1939 range of cars is the introduction of three new models—8-h.p., 10-h.p., and 12-h.p.—with independent front-wheel suspension. In other respects the vehicles follow the Standard general practice, and in view of their comparatively low prices are likely to be popular during the coming season. The 9-h.p. and 14-h.p. "fours" and the 20-h.p. "six" are being continued with only minor changes. Standard car prices range from £125 to £325; with the exception of the 8-h.p. open tourer and a 12-h.p. drop-head coupé all bodywork is of saloon type.

As the result of an amalgamation between the two concerns the Talbot cars are now known as the Sunbeam-Talbot. Although 21- and 27-h.p. "sixes" are available, chief interest from the point of view of the medical man centres on the four-cylinder Ten, which is offered at £265 in saloon form and at £285 as a foursome drop-head coupé; the principal modification is the increased bodywork space, resulting from the engine having been moved forward three and a half inches in the frame.

Triumph, Vauxhall, and Wolseley

Another popular car is the Triumph, the range of which comprises 16-h.p. "six" and 14-h.p. four-cylinder models. Chief alterations in the latest models are larger engines, wider radiators, more roomy bodywork, and the addition to the saloons of a 16-h.p. roadster coupé. Externally the Triumph cars have an attractive appearance, and their prices range from £312 to £450. For the 1939 season the four-cylinder Vauxhall Ten with integral chassis and bodywork frame, together with independent front-wheel suspension, is being continued with but slight modifications. The chief feature of the Vauxhall programme is the introduction of a new Twelve-Four; replacing a "six" of the same horsepower, this embodies all the special features of the Ten and is offered at the attractive price of £189 for the standard saloon and £198 for the *de luxe* sliding-roof saloon. The Vauxhall Fourteen six-cylinder model is being continued at £230 with many new features, including a more roomy saloon body, hydraulic brakes, synchromesh gearbox, and adjustable steering wheel. Finally there is a 25-h.p. "six" at £345. A special feature of the Vauxhall series is the attention which has been paid to the matter of economy in fuel consumption.

Concentrating its activities largely on six-cylinder cars, the Wolseley company, in addition to continuing the 12/48-h.p. four-cylinder model and 21-h.p. and 25-h.p. "sixes," has introduced three new chassis with power units rated at 14/60 h.p., 16/65 h.p., and 18/85 h.p. All are fitted with powerful silent-running engines and four-speed gearboxes with synchromesh gears on second as well as third and top speeds; the prices range from £245 for the 12/48-h.p. saloon to £395 for the 25-h.p. chassis with five-seater saloon body.

Special Motor Bodywork

Despite the excellent finish of what may be termed the mass-produced modern vehicle, which fully meets the requirements of the majority of medical men, there is still a section of the motoring public which prefers to make its car purchases in chassis form and have bodywork fitted to meet individual preferences. Because of this a section of the show is still devoted to a display of special coachwork, not necessarily for the high-powered car, but also for such popular makes as Austin, Hillman, Morris, Standard, and Vauxhall. In this section, as being useful for doctors, attention may be drawn to the Tickford (Salmon and Sons) and Redfern-Maltby (Maltbys Motor Works and Garage Ltd.) "all-weather" vehicles, which can be quickly and easily altered from being entirely closed to fully open form and vice versa. Some excellent specimens of British coachbuilding are also to be seen at the stands of Mann, Egerton and Co. Ltd. and Offord and Sons Ltd.

At the stand of the last-named firm there is a 25-h.p. Wolseley seven-seater limousine the Offord body of which has been specially designed for the use of a lame person or invalid. Briefly, the construction is such that half the usual wide rear seat is omitted so that its place can be taken by a comfortably upholstered spring-mounted invalid's wheeled chair. Thus, the passenger for whom it is intended can take his seat in it either in, or at the door of, the house and then be wheeled up light detachable runners into the car, the chair, with its occupant, being then manoeuvred and securely clamped in position; the runners when not in use are detached and carried in the luggage boot of the vehicle. This arrangement can be embodied in new or old cars provided the doors are of sufficient width. I learned at the exhibition that the demand for conversions is proving much larger than was at first anticipated.

Motoring Accessories

As usual, the galleries at Earl's Court are devoted to an almost bewildering display of motor accessories. At this time of the year, when severe weather conditions may be experienced, attention may be drawn to the display of radiator muffs to keep the engines warm when cars have to be left standing in the street, and to the numerous non-freezing preparations for radiators and garage-heating lamps and stoves, which prevent the freezing-up and possible cracking or bursting of engine cylinders and radiators during frosty weather. There are also several new appliances for warming the interior of cars in cold weather. Among these is the A.C. made by the A.C. Sparking Plug Co. Ltd. Actually the core of this new heater is itself a tiny honeycomb radiator, through which a small quantity of hot water is by-passed from the engine radiator, a miniature electric fan being mounted behind it to drive heated air into the interior of the car. As the quantity of hot air supplied depends upon the spread of the fan it is possible to adjust the temperature within the car over a wide range. The makers state that the ideal position for the heater, which is made to operate in conjunction with 6- or 12-volt batteries, is centrally in front of the change-speed gear lever; it can be fitted to all cars having a pump or impeller in the water-circulating system. Other car heaters include the HaDees exhibited by S. Smith and Sons Ltd., and the Tropic-Aire appliance of S. Guiterman and Co. Ltd.

Medical men, especially those whose practices are located in country districts, would be well advised to have the bulbs of their car lamps overhauled occasionally and possibly renewed. Like those used for house-lighting purposes, car bulbs are regarded as having a useful life of about 1,000 hours, after which their lighting capacity falls and there is a risk of the filaments breaking. It is advisable, too, to carry a supply of spare bulbs. Small cases containing spare bulbs are made by Lucas's and the other principal lamp manufacturers, and they can be ordered through any local garage.

Reports of Societies

NOMENCLATURE OF DISEASES OF THE FUNDUS

In newly taking the chair of the Section of Ophthalmology of the Royal Society of Medicine on October 14, Mr. MALCOLM L. HEPBURN devoted his address to a discussion of nomenclature. He considered that the time had arrived when it was desirable to reconsider the nomenclature of fundus diseases in the light of present pathological knowledge. In the past, when few eyes were subjected to microscopical examination, it was necessary to be content with pictorial descriptions of the condition as seen with the ophthalmoscope. As the details of even the same type of case might vary from time to time the name given to any particular picture often depended on the stage in the pathological processes at which the case was first seen. Sometimes the same name had been applied to entirely different fundus pictures and a different name to the same picture. Mr. Hepburn showed a number of examples, some of them from classic work, though he was careful to preserve the anonymity of all of them. The present position was that several entities were entirely unnecessary and failed to form the basis for reasonable classification, while a number were actually misleading. The phraseology still in common use was not infrequently ambiguous and even devoid of meaning; but until there was universal agreement regarding the names that should be retained and those that should be given up it was impossible to begin any reconstruction of a new nomenclature.

Mr. Hepburn suggested for a new nomenclature that (1) every disease of the fundus should be described in terms of one pathological whole, with reference to choroid or retina or both, and comprising all the details contained in the picture; (2) when the pathology was unknown the resort to a pictorial or a non-committal pathological term was unavoidable; and (3) before coming to a decision on any particular fundus condition the clinical history should always be considered.

BIOCHEMICAL ASPECTS OF GROWTH

At a meeting of the Manchester Medical Society on October 5 Professor H. S. RAPER delivered his presidential address on some biochemical aspects of growth.

Professor Raper said that the problems of growth were in part biochemical, since fundamentally the process involved the synthesis of new living matter. Contributions to the subject had come from very varied quarters during the present century, and had all shed some light on it. Studies of the material basis of growth in animals had shown that new protoplasm could only be produced if certain amino-acids were provided. The presence of these "essential" amino-acids in dietary proteins had been made the basis of important recommendations as to the minimum protein requirements in human nutrition. The use of x rays in the investigation of protein structure had already revealed something of the architecture of the

protein molecule, and as protein seemed to be the essential basis of protoplasm this knowledge was valuable to the biochemist seeking to determine the mechanism of protein synthesis in the living cell. A fascinating field for the study of protein synthesis had been opened by the discovery of crystalline virus proteins. These were able to multiply automatically inside plant tissues and probably represented the most elementary process of growth yet known.

Growth Stimulants

Many substances had now been discovered which might be classified as growth stimulants. Some, like certain of the vitamins, the growth hormone of the anterior pituitary gland, and the growth-promoting substance present in embryonic tissues, had a general effect. So far as could be seen at the present time they played the part of catalysts in promoting the synthesis of new living material, though it was possible that some of them might be essential components of protoplasm. Other growth stimulants were more specific and appeared to act only on certain types of cell. In this category came those sex hormones which were responsible for the development of secondary sex characters and for changes in the sex organs occurring during oestrus and pregnancy. The action of these substances was allied to that which took place in the differentiation of the embryo. It seemed likely that this action was truly catalytic because it could be imitated, in some instances almost exactly, by synthetic chemical agents which were not allied in structure to the naturally occurring hormones.

The fact that many bacteria would grow and multiply in an inorganic medium if a suitable source of carbon was supplied suggested at first sight that growth promoters were not essential to them. What was more likely, however, was that such organisms were able to synthesize all they required from the elementary substances supplied, and these included growth stimulants because it had been shown conclusively that bacteria which would not grow in such media grew well if certain substances were provided in small amount. The addenda required comprised vitamins (particularly of the B group), unknown substances present in animal tissues, and certain amino-acids.

The study of plant growth had also received a new impetus from the discovery of auxins, which might be styled plant growth hormones. These were present at growing points in the plant and were probably growth catalysts, since their action might be largely imitated by synthetic organic compounds of quite a different nature. A survey of the various fields of study in which the biochemical aspects of growth were being investigated gave good grounds for the expectation that in the coming years a much clearer understanding of the process would emerge.

SOME ASPECTS OF HEREDITY

At the opening meeting of the session of the West London Medico-Chirurgical Society, held at the De Vere Hotel, Kensington, on October 7, the new president, Dr. MAURICE SHAW, gave an address from the chair, taking as his subject "Heredity." He gave a careful exposition of the laws of Mendelism, and followed this with an exposition of the work of T. H. Morgan of Columbia University, only second in importance, he said, to that of Mendel in building up the theory of the "gene." Dr. Shaw appealed for greater interest on the part of the medical profession as a whole in the science of eugenics. This was the more important because orthodox medicine tended to be dysgenic in its action. The profession was largely responsible for perpetuating dominant defects which, but for its "misguided efforts," would probably die out. The insulin treatment of diabetes was probably the most obvious example. It was known that diabetes might be hereditary, although its exact mode of inheritance was uncertain. If untreated, a very large number of young diabetics would

never survive to marriageable age. The introduction of insulin had entirely altered the picture, and a majority of this type of diabetic might now be expected to marry, ensuring a steady increase in the incidence of the disease in the next few generations. Tuberculosis was another example if the hereditary predisposition, which was denied by some quite competent observers, were accepted; though inasmuch as tuberculosis required an environmental as well as a hereditary factor, there was more chance that the disease might ultimately be eliminated.

Ought not the medical profession, by interesting themselves in eugenic theory and practice, to try to counteract a little of the harm they inflicted upon the race by their wanton interference with Nature's principle of natural selection? This was scientifically possible, for it merely meant the application of the principles of stockbreeding to human affairs. There were several lines along which the problem could be tackled, one of the most obvious being that of sterilizing all individuals who might distribute a harmful gene among the general population. A difficulty in the approach to eugenics along the path of sterilization, however, was that mutations, whereby all harmful genes must originally have arisen, could not be prevented from occurring. In conclusion, Dr. Shaw discussed some purely medical aspects of heredity, especially the inheritance of blood groups. A vote of thanks to him was accorded on the proposition of Dr. JAMES BURNFORD, seconded by Mr. A. E. ROCHE.

The 843rd ordinary meeting of the Brighton and Sussex Medico-Chirurgical Society was held at the Royal Pavilion, Brighton, on October 6, when the president for the year, Dr. J. G. Hayes, gave his presidential address, entitled "Thirty Years of General Practice," and several members then related their own experiences during a similar number of years.

Local News

ENGLAND AND WALES

New Laboratories of the Metropolitan Water Board

The new laboratories of the Metropolitan Water Board—a three-story building containing some fifty laboratories and supplementary rooms with the most modern equipment for water examination—were opened by the Minister of Health (Dr. Walter Elliot) on October 17. The building has been erected at Clerkenwell, adjacent to the head office of the Board, on the very spot where, in 1613, Hugh Myddelton brought the "sweet waters" of Hertfordshire to what was then the confines of London. The key with which Dr. Elliot performed the opening ceremony was contained in a box made of the oak used by Myddelton in constructing the "round pond" which formed New River Head. The Metropolitan Water Board has had its offices at this site ever since, in 1904, it took over the water undertakings of London, but its laboratories have been in Nottingham Place, Marylebone, in houses built for other uses. There for a third of a century "the watch on the water" has been maintained day after day, a vast routine examination of samples has been carried out together with a great deal of original research. During last year, for example, the number of bacteriological samples taken was over 22,000, of chemical samples nearly 6,000, and of biological samples over 3,000. One remarkable piece of work carried out for many years at Nottingham Place has been the routine photomicrography of the algal content of the water from all the Board's storage systems. Some 22,000 such photographs are now housed in albums. The work of the laboratories, however, has suffered from restricted space in not quite suitable

premises, and now it is to be transferred to Clerkenwell, where the new laboratories are worthy of the leading water authority in the world and the pioneer of purification processes. Unfortunately, neither of the two men whose names will always be associated with this work lived to see its completion. Sir Alexander Houston was for twenty-eight years director of water examination, and on his death in 1933 Lieutenant-Colonel C. H. H. Harold was appointed to succeed him. Harold's sudden death in July last cast a shadow over the new enterprise which owed so much to his initiative and imagination. He had visited more than twenty cities in the United States and Canada to ensure that the choice of services and equipment for the new laboratories was in line with the most modern practice.

The main function of the new laboratories will be to organize mass performance of special water tests supported by highly technical examinations. The tests fall into three sections to which, roughly speaking, the three floors of the laboratory correspond—namely, biological on the ground floor, bacteriological on the first floor, and chemical on the top floor—and the administrative department includes the arrangements for the collection of samples and their interpretation and statistical recording. The laboratories are disposed on a chain principle so that the work proceeds as far as possible from one room to the next. The bacteriological section is of particular interest. It has been so designed that cleansed sterilized receptacles receive their quota of media and are plugged and sterilized before arriving at the media stockroom. From thence they travel to the main general laboratory, and after the samples have been put up they are trolleyed into the controlled temperature rooms, which operate respectively at 22°, 37°, 42°, and 45° C. After incubation the tubes are sorted in the sorting-room, and the positive tubes pass on to the subculture room for further study. A dark counting-room adjoins for the performance of special counts and the reading of agglutination results. One feature to which special attention was drawn was that rooms are being used instead of a number of box incubators, a departure which permits of enormous expansion in the future. The arrangements in the 22° C. room are also of interest, as this is a difficult temperature to maintain. The temperatures of all the rooms are thermostatically controlled and recorded, and the amount of air current regulated in accordance with humidity readings. Special ventilation is also employed to minimize condensation in view of the large amount of fluid being incubated.

London Medical Exhibition

To the London Medical Exhibition, which has been held during the past week at the Royal Horticultural Hall, Westminster, about 120 firms contributed, and the stands as usual were filled with a varied display of products. So varied, indeed, that one visitor at least wished that exhibitors, having learned many of the arts of display, might emulate the economy of the West End milliner who devotes her whole window space to a single bonnet. It was quite refreshing to come upon a stand which concentrated on a single article—rubber gloves and nothing else, or a brand of mustard, or a medicated wadding. When it comes to medicinal and food preparations—and more than half the stands were of that character—the variety almost took one's breath away. Quite a dozen firms showed sulphanilamide under some name or other. There was also what Sir Henry Dale at Guy's Hospital the other day described as a "bewildering and redundant profusion of symptomatic remedies." Surgical instruments were less conspicuous, and in view of the place which physical medicine now occupies there did not seem to be quite an adequate representation in that field. On the other hand, there were several exhibits of great interest to the ophthalmologist; hearing aids also were more in evidence than ever before. A number of bookstands, including that of the British Medical Association, gave a pleasant relief. More than one stand was devoted solely to contraceptive appliances, one of them announcing that seven of its products were on the approved list. An instrument to which a good deal of attention was paid

was an electrical stethoscope in which the incorporation of a frequency range selector made it possible for the operator to emphasize sounds of one particular tone; it was also provided with a second set of auricles, enabling two physicians to participate simultaneously in an examination. Another device was a portable resuscitator for respiratory emergencies—drowning, carbon monoxide poisoning, anaesthesia, shock, and war gases. Equipment for oxygen therapy was demonstrated, including the installation of pipe-lines in hospitals and nursing homes for the supply of gas from a central cylinder to various points in the wards.

Central Midwives Board

It was reported at a meeting of the Central Midwives Board for England and Wales on October 6 that, acting on the powers conferred upon him by Minute 40 of the meeting of July 7, 1938, the chairman had approved as lecturers: C. M. Gwillim, M.D., F.R.C.S., A. L. Gunn, M.D., F.R.C.S., W. C. W. Nixon, M.D., F.R.C.S., J. Sakula, M.D., R. Christie Brown, M.S., F.R.C.S., Albert Davis, M.D., F.R.C.S., and R. L. Dodds, M.B., F.R.C.S. Approval as lecturers was also granted to Mary Florence Bignold, M.B., Ch.B., Samuel Davidson, F.R.C.S.Ed., and Robert Newton, M.D. The chairman reported that acting under his vacation powers he had decided to grant applications for the inclusion of Radcliffe Infirmary, Oxford, and the Sussex Maternity and Women's Hospital in the list of institutions approved for the special instruction (required by the Board's ruling on the administration of nitrous oxide and air by midwives) in the essentials of obstetric analgesia and in the use of a recognized apparatus.

IRELAND

Some Vital Statistics for Northern Ireland

The report of the Registrar-General for Northern Ireland, which has just been issued, records an increase in the death rate and a reduction in the marriage and birth rates. The number of births registered was 25,412, a rate of 19.8 per 1,000 of the estimated population; this decline finds a parallel in England and Wales, though in the latter area it is more steep and the rate is lower. The general death rate was 15.1 per 1,000 of the estimated population, being slightly higher than last year, but in common with the experience in England and Wales demonstrating a general downward trend over the past twenty-two years. A severe epidemic of influenza in the first quarter of the year accounted for an unduly large number of deaths, while deaths from diphtheria, scarlet fever, and diarrhoeal diseases in children showed marked decreases. The number of deaths from influenza was 1,148, giving a rate of 0.9 per 1,000 of the population, compared with 0.21 in 1936. The general downward trend in the death rate from tuberculosis continued, the rate being 0.98 per 1,000 of the population, a figure somewhat higher than that for Scotland and England and Wales, but lower than that for Eire. It is noted that almost one-half of the deaths from all forms of tuberculosis during 1937 occurred between the ages of 15 and 35 years. The cancer death rate was 1.3 per 1,000 of the population, maintaining a fairly steady rate. The most frequent sites of fatal cancer among males were: stomach, 216; intestines, 114; rectum, 65; prostate, 47; and liver and gall-bladder, 35. Among females the stomach was affected in 188 cases; intestines in 127; breast in 115; uterus in 108; rectum in 42; and the liver and gall-bladder in 50. The death rate from diseases of pregnancy and childbirth showed a welcome decrease from the figure of 1936, the rate having fallen from 6.06 per 1,000 births to 5, this figure being just a little above the previous lowest figure (that of 4.8 in 1927). Infant mortality continued to take its toll, the figure being 1,969, representing a rate

of 77 per 1,000 births registered, the same as for 1936. The rates during 1937 and 1936 (respectively) were: in England and Wales, 58 and 59 per 1,000 births; Scotland, 80 and 82; and Eire, 73 and 74. The infant mortality for the county borough of Belfast was 94 in 1937, as compared with 109 (1932), 101 (1933), 81 (1934), 112 (1935), and 101 (1936).

Royal Maternity Hospital, Belfast

The Registrar of the Royal Maternity Hospital, Belfast, has issued his annual report, in which is recorded a highly successful year's work in the hospital. Full clinical details of the twenty deaths out of 1,729 admissions (mortality rate of 1.15) are given; in 1936 the rate was 1.24, and in 1935 1.6. Of the total admissions 396 were emergencies, and no fewer than eleven of the twenty deaths occurred among these patients. The maternal morbidity rate was 6.7 per cent., as compared with 8.2 in 1936 and 4.9 in 1935. No maternal deaths occurred in the cases of eclampsia, and there was only one fatality in the thirty-two patients with heart disease, of whom twenty-four were suffering from mitral stenosis. Multiple pregnancy occurred in twenty-one cases; there were eighty-five deliveries as breech and twenty-one as persistent occipito-posterior presentations. Caesarean section was performed on fifty-seven occasions, in the majority of the cases on account of contracted pelvis or disproportion; the lower segment operation was the method chosen in forty-two instances. Other tables give full records of forceps deliveries, accidental haemorrhage, and the induction of abortion or premature labour. Valuable features of this report are the details and tables relating to foetal mortality and premature infants. The information concerning premature infants is not included in all maternity hospital reports, and is a practice which might be more widely adopted.

Dublin Fever Hospital Board

The annual report of the medical superintendent of Cork Street Hospital, Dublin, appears this year as part of the first report of the Dublin Fever Hospital Board since the change from voluntary to municipal control. A brief glance at the statistics given by Dr. McSweeney for the year 1937 reveals a general improvement on the corresponding figures for the previous year. The general mortality rate was 6.66 per cent., as against 8.39 for 1936 and 8.71 for 1935. There was a sharp increase in the incidence of scarlet fever at the end of 1935, which continued through 1936; this incidence fell in 1937, the number of cases treated being 624, as compared with 976 the previous year. While diphtheria continued to be of a high degree of virulence and accounted for some 40 per cent. of the total deaths in the institution, the case mortality of 9.1 per cent. shows an improvement on the 1936 figure of 12.57. Of the fifty-nine fatal cases thirty-five were moribund on admission. Dr. McSweeney comments that "it is a matter for regret that cases do not receive medical aid at an early stage of the disease. . . . It is still not uncommon in Dublin for patients to be admitted to hospital who have been ill with diphtheria nearly a week." Some form of diphtheritic paralysis was exhibited by fifty-eight patients; nine with respiratory paralysis were treated in the Bragg-Paul pulsator and recovered. There were two deaths among these fifty-eight cases. An investigation into the problem of diphtheria in Dublin with particular reference to ascertaining the prevailing types of organism has been in progress in the hospital under the auspices of the Irish Medical Research Council since October, 1937. Fifty-eight cases of meningitis were dealt with during the year, of which thirty-five were of the meningococcal variety. The mortality among these thirty-five cases was 60 per cent., as compared with 78.2 per cent. in 1936. The better results, the report states, were partly due to the use of American sera and to the employment of chemotherapeutic

remedies as an adjuvant to serum. Several unusual forms of meningitis were encountered during the year: one case of paratyphoid B infection of the meninges is believed to be the first to be recorded in the literature. On the subject of chemotherapy Dr. McSweeney says that some cases of puerperal septicaemia, due to the haemolytic streptococcus, were found to be quite resistant to this form of treatment, but that the sulphanilamide group of preparations was proving a specific remedy for erysipelas and had replaced serum therapy in the practice of the hospital.

Correspondence

R.M.B.F. Christmas Gifts

SIR,—Each year for nearly thirty years Christmas gifts have been sent, in the spirit of good cheer, through the agency of the Royal Medical Benevolent Fund, to members of medical families whose poverty and distress, often coupled with infirmity, illness, and loneliness, have made their ageing days a pitiful existence. Those who have received the gifts are old medical practitioners or their widows and daughters, who are debarred from any luxury or lighter pleasures in life. What luxury or extra pleasure can be enjoyed on an income of £90 a year, which has to meet all the necessities of life?

Will you help us again in making this appeal known to your readers? The Committee has felt that this is a matter which always appeals to the warm and generous hearts of medical men and women, and that no broadcast appeal should ever be made to the general public. "The family" to whom our gifts are sent is a very large one, and we need over £1,000 if each one of our beneficiaries is to receive the customary Christmas gift of 30s. This can be done only if we receive the same generous response as last year. I know that the present days are difficult, but everyone could spare a small contribution to add to the pleasure of those whose lives are sad at Christmas time. Please send donations, large or small, to the honorary treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

I thank all for their help and co-operation in past years in our Christmas gift scheme, and shall be deeply grateful for a generous response to this appeal.—I am, etc.,

THOS. BARLOW,
President

Civil Medical Organization in War

SIR,—In common with most, if not indeed all, of your readers, I have been greatly interested in your leading article (October 8, p. 749) and the correspondence arising therefrom in your issue of October 15 (p. 810). Since the year 1930 I have been a member of five committees which have met under the aegis of three Government Departments. Each one of these committees was appointed to consider the provision to be made, by hospital beds, ambulance services, etc., for casualties arising from air raids upon London. The first four of these committees expired without any indication as to why our work was terminated and without having produced any definite scheme. We certainly accumulated an enormous mass of valuable information, but, so far as I am aware, it was not translated into any practicable scheme. Moreover

inasmuch as personnel of each of the four committees, with the exception of myself, was substantially altered in each committee, a good deal of valuable time and energy was inevitably wasted in starting the work of each committee.

The fifth committee was the so-called Wilson Committee, appointed by the Secretary of State for Home Affairs in the spring of this year. This committee, of which again the personnel, with the exception of myself, was entirely new to the work, certainly did some strenuous work and presented an interim report of its findings to the Minister of Health about the middle of July. The interim report dealt almost entirely with certain important principles which required the approval of the Minister before any detailed consideration could be given to their practical application. The committee adjourned after the presentation of its interim report and has not met since. Personally, I think it is just as well that it has not met, as it will be quite obvious to everyone that the unexpectedly rapid development of events in Europe during the months of August and September made it essential that the problems involved in A.R.P. measures were of so urgent a character that at that period they could be dealt with much more expeditiously by the direct executive action of the staff of the Ministry of Health than by the cumbersome procedure associated with *ad hoc* committees. Herein, therefore, lies the explanation for the lack of any carefully-thought-out schemes for hospital casualty services, ambulance services, and first-aid "posts," etc.

The next point to which I should like to refer is that in my judgment far too much attention has been concentrated hitherto upon the provision *within the County of London* of an enormous number of hospital beds for casualties. The minds of nearly all those with whom I have come into contact on this problem seem to me to be obsessed with this idea of providing 50,000 or more beds in London for such casualties, whereas it would seem to me to be infinitely more important to provide the *minimum* of beds for such purposes in London and the *maximum* outside London. A friend of mine discussing this point with me some time ago said quite truly, "When 50,000 beds are required in London to deal with air raid casualties, the war is over." I asked him why, and his answer was: "Such figures could only become necessary because our anti-air defence organization had completely broken down"; and, he added, if that were so, "not even 50,000 beds would be any use at all, as the population of London would be completely at the mercy of the attacking air bombers." Whether my friend is right or wrong, the fact remains that the policy of concentrating large numbers of beds for casualty cases in London is open to many serious objections for other reasons. For example, no serious consideration seems to have been given to the legitimate needs of the sick poor—whether acute medical, surgical, or maternity, etc.—nor to the immense difficulties which might arise in connexion with breakdowns in the supply of electric current, gas, water, and other public services, nor to the difficulties of transport, especially of perishable foods, fuel, etc. One cannot ignore either the enormous additional risk to the lives of a large number of skilled medical, nursing, technical, and other hospital staff, particularly in the cases of the large medical school hospitals, if, in fact, they were concentrated under one roof, as they have to be if such schemes as those outlined in the case of University College Hospital were carried out. There is no particular reason why a medical school hospital should enjoy any less risk from being blown up by a high-explosive bomb than any other building, but if it did happen the loss of skilled staff would be very

serious in a period of emergency. The risk does not appear to me to be justifiable. I would rather advocate the division of the County of London into five regional areas; that in each of those areas the estimated number of beds required should be divided up between twenty or even thirty hospitals, voluntary and municipal; and that the surplus staff of the voluntary hospital medical schools and other voluntary hospitals should be organized to form "mobile units" which would serve not only any of the hospitals in the regional area but also, if possible, the associated hospitals (base hospitals, as they are called) on the outskirts of London. Such a scheme would greatly reduce the risks to patients and staff, and greatly lighten the burden of transport, both for the movement of patients within and without the County of London. Moreover, it would not seriously interfere with the provision of a reasonable amount of hospital accommodation for the "sick poor" or the progress of medical education.

There are two other matters of fundamental importance which have not been properly organized up to the present—namely, ambulance services and first-aid posts. The former is, of course, an essential element in any A.R.P. scheme for dealing with casualties either in hospital beds or at first-aid posts, and its importance needs no elaboration from me, but it is nevertheless a remarkable fact that up to the last moment there was no properly organized ambulance service scheme for London. The position with regard to first-aid posts was even worse. It is not an exaggeration to state that, generally speaking, the scheme was hopelessly inadequate when considered from the point of view of London as a whole. Those who are familiar with the problems involved in the matter of hospital bed accommodation for casualties and ambulance services will, I feel sure, agree with me that unless there is a really first-class organization for first-aid posts, any scheme, however perfect, for hospital beds and ambulance services will completely break down because they would be "flooded" with masses of minor casualties which could and should be dealt with on the spot and sent home afterwards.

Finally, I would add my firm conviction that any efficient scheme for A.R.P. in London must include under "unit control" all hospital beds, ambulance services, and first-aid posts. Any division of authority and control between these three component parts of the scheme will prove in practice to be fatal to success. I need hardly add that I include all voluntary and municipal hospitals in the words under "unit control."—I am, etc.,

London, Oct. 16.

FREDERICK MENZIES.

SIR,—Your leading article and the letters you have published are depressing. It is easy to lose one's temper, almost as easy to impart to a political friend (or one's M.P.) authentic particulars of gross incompetence within one's own knowledge. Any man over fifty knows the utter futility of either reaction. Either one's political friend will do nothing whatever or, more probably, he will use the information simply to help him to score some point in the party game.

We, as a profession, can play a nobler part. We can, building on the facts already assembled, make a complete register of our individual resources and a detailed plan for the utilization of our services. I am interested (for obvious personal reasons) in a minority of our profession. On the *Medical Register* are the names of hundreds of men and women whose *immediate* value for what the public would call medical work is negligible. Probably, even under the present chaotic conditions, a few of them would be utilized in the services for which their special

training and experience have fitted them, but only a few. I am prepared to argue—at almost any length—that, even in war-time, statistical knowledge is of national importance. But I simply cannot conceive of a well-middle-aged professor of medical statistics being entrusted with any national statistical work whatever. The fellow is a *medical* man, and what on earth have “doctors” to do with statistics? The same remark applies to other “doctors” whose normal avocations are even more remote from clinical work.

The objection I so crudely phrased above is sound. A “doctor” is different from other people. As a technician he may have become hopelessly inefficient, but nobody who has been through the mill of a medical curriculum is ever again a “layman.” There must always be a number of duties which any doctor can perform better than a layman. I could make a long list of them. Here is one that leaps to the eyes. If literally millions of children and women are to be evacuated from towns into villages and the open country, emergency sanitary organizations must be devised. The working of these will need much supervision. No doubt elderly sanitary inspectors or retired N.C.O.s of the R.A.M.C. would, from the technical point of view, do such a job as well as doctors, but the real doctor would have a certain prestige with the laity which has a psychological importance. I need not go on with the list. The point I am trying to make is that *all* of us can be fitted into a national scheme, given time and thought. Simply for the pleasure of doing an intellectual job of work well it is worth while carrying on what has been begun. No doubt official contempt, general indifference, and personal vanities will mar the plan. But we shall have done our duty, and although truth seldom prevails it is never quite impotent. —I am, etc.,

Loughton, Oct. 15.

MAJOR GREENWOOD.

SIR,—It is indeed time for plain speaking. No one is likely to hand any bouquets to the Ministry of Health or the Home Office for their handling of the preparations to deal with air raid casualties, but before the stones are hurled would it not be advisable to examine the glass in the B.M.A. windows?

The B.M.A.'s scheme of national medical service is based upon the perpetuation of the individual practitioner as a unit to himself, the utilization of the general voluntary hospitals as a separate unit receiving funds but no control from the local authority, the control of the health services of the country by means of practitioner representatives on the public health committees of the local authorities.

In the face of such proposals, you, Sir, expect the central authorities to prepare comprehensive schemes capable of meeting national emergencies. In a crisis there must be leaders with powers; toes will be trodden upon and someone may suffer the loss of a little prestige, but no proper organization is possible without powers. The preparation of any scheme which is to be of value is dependent upon the local authority having control of all the medical services in its area. The present position is chaotic. That being so, is it not time that the British Medical Association helped the Government by formulating at once a scheme of national medical service which will give the local authorities the necessary powers to enable them to meet a crisis? That at least would be helpful.—I am, etc.,

Boston, Lines, Oct. 10.

W. G. BOOTH.

Air Raid Precautions

SIR,—The evacuation of school children in a time of crisis presents difficulties and needs organization. I cannot say that I have been favourably impressed by the methods employed in the recent crisis. I suggest that if time and money permit permanent school camps be established in the country. They should have some permanent buildings, sufficient to house a number of school children transferred from towns to receive the benefits of country life. The camps should be capable of rapid expansion so that their population could be increased with ease. There is no hardship in living under canvas, and canvas should be used if there are not enough huts. The water supply, sanitation, sick-room accommodation, and medical service should be arranged for quiet times and to meet times of crisis. Non-perishable food could be in store.

Such a scheme would have many advantages both in peace and war. It would be better than a hurried evacuation to country places that have not received notice and can only with difficulty provide accommodation, and that of an unsuitable character. Many cottages in the country have a scanty and barely adequate water supply for the usual inhabitants; an influx of town children would be beyond their capacity. Town children are used to turning on taps, pressing electric switches, and pulling plugs. It would take time for them to assimilate cottage ways without doing damage to their hosts and themselves. Town children recently were evacuated with two days' rations. Unless there was a better organization than was set recently there would be a shortage of food for the next two days, and what then? Charity would have to step in.—I am, etc.,

London, W.1, Oct. 13.

CHARLES M.

SIR,—The appalling damage caused by modern explosives in densely populated districts is well known. We read, for instance, that during a bombardment of Shanghai, the total number of casualties from this shell must, of course, have been very much higher than if London or any other city was ever subjected to bombardment on a large scale the casualties would be greater than could be dealt with even by the most efficient medical service.

Apart from evacuation, which takes time, and could not be carried out quickly enough in the event of the sudden outbreak of hostilities, there is one plan which could reduce the number of casualties to a reasonable level, and this is the provision of adequate shelters. In a recent bombardment of Madrid 205 shells were fired into the city with a loss of only four persons killed and but thirty injured. Such an extraordinarily low casualty list is due mainly to the fact that adequate shelters, proof against anything but a direct hit from a large shell or bomb, are provided in Madrid.

Either there is a risk of war or there is not, and so long as this risk remains in Europe it is essential in my opinion that adequate shelters should be provided in British cities if we wish to keep civilian casualties in bombed areas to a sufficiently low limit so that each casualty can obtain proper medical and surgical attention. I feel convinced that the time for providing these shelters is now, and I believe that the majority of doctors, and in particular those with war experience, will agree with me for my observations are based on a careful consideration of what modern warfare means. It is useless to provide the most efficient medical service conceivable if the number of casualties is going to be tens of thousands all occurring in the space of a few minutes.—I am, etc.,

London, W.1, Oct. 16.

CLEMENT FRANCIS, M.B.

Decline of Breast-feeding

SIR.—I hope that Dr. J. C. Spence's admirable paper on breast-feeding will lead to some practical results. He points out, and it is very important, that the handling of the problem lies with the woman, and tells of what a sagacious woman can do. But in this case matters are worse than in the parable of the ten virgins; for one wise virgin there are nine foolish ones. Improvement of the position can only come with a real education and training of pupil-midwives, health-visitors, and nurses. It is not enough for the nurse to say, with the solemn emphasis of an article in the creed, "Breast-feeding is best," and then, as soon as some trivial difficulty occurs, advise weaning.

The place for such training is in the paediatric service of a teaching maternity hospital, which includes a follow-up baby clinic. In Edinburgh at the Royal Maternity Hospital we have such a service, and theoretical and practical training in breast-feeding and infant hygiene is given to the pupil-midwives. But such training should be standardized by regulation and checked by examination. And it is essential that health-visitors should receive similar training. It is only by teaching that we can obtain a national service of "sagacious women" trained in the art of breast-feeding. The key to the problem is the utilization of our maternity hospitals for this training.

Meantime, the propaganda value of Dr. Spence's clear, wise, and witty paper is very great. I suggest the Ministry of Health should place a copy in the hands of every midwife and health-visitor throughout the land.—I am, etc.,
Jinburgh, Oct. 16. CHARLES McNEIL.

SIR.—As a fanatic on breast-feeding I was much interested in the article by Dr. J. C. Spence. I agree with him that the vast majority of failures are due to mismanagement, and for this the medical and nursing professions are largely to blame. There are still far too many doctors who take no interest in the baby's food and far too many nurses who fly to a bottle at the first difficulty. Even adequate supervision during the first fortnight of the puerperium the average mother finds most difficult when she starts to take up her multitudinous household duties. It is then that the vicious circle starts: insufficient milk → crying hungry child → sleepless mother, father, and neighbours → anxious tired mother → further decrease of breast milk. If expert advice is not obtained immediately artificial feeding is started. It is at this time that the advice of the family doctor should be most helpful. The mother is often not sufficiently fit to push the pram to a welfare centre, and by the time she does the breast milk may be completely lost. Once lost, it is difficult to get it back without complete hospitalization, which is nearly always impracticable. A little helpful advice and encouragement during the second fortnight of the puerperium will often reverse the vicious circle, and the milk supply increases rapidly.

Ten years ago I avoided resorting to bottles at all costs, but now I find that the results are better if a little judicious complementary feeding is allowed. The psychological effect of a contented and well-satisfied baby has an almost miraculous result on the supply of milk, which increases by leaps and bounds, so that the little is soon abandoned. The intense fatigue felt by the lactating mother at this stage can be successfully moved by large doses of iron.

I agree with Dr. Spence that it is a mistake to be too debound about times of feeding. An occasional night feed is better than a sleepless household, but if the child's sense of psychological security is not disturbed by maternal anxiety regular feeding soon becomes automatic.

I do not consider test-feeding as over-mechanization if used with common sense. I have several complete records of test-feeds from birth to 9 months, and many for shorter periods. Intelligent mothers tell me, and I know from personal experience, that regular test-feeding often saves time, trouble, and anxiety. Calculating caloric values and ounces per pound is also useful as a general working basis, but it must be remembered that all these rules are made to be broken in individual cases. Highly trained maternity nurses often do not realize this, and impose far too rigid a routine. In looking through 100 consecutive cases from my records I find that 82 per cent. of mothers breast-feed their babies for over three months and 70 per cent. for over six months, when extra foods are gradually introduced, and complete weaning takes place at nine to ten months.

I am convinced that if only a more active interest were taken in the subject by the medical profession the percentage of breast-fed babies would greatly increase.—I am, etc.,

Chippenham, Wilts, Oct. 10.

JOAN F. HICKSON.

SIR.—Commenting on the very stimulating paper by Dr. J. C. Spence on the modern decline in breast-feeding, may I make one or two suggestions.

New Zealand, I think, is still far ahead of this country in the advocacy of breast-feeding. Twenty-five years ago or more the Plunket Society (now known as the Royal N.Z. Society for the Health of Women and Children) taught the fundamental importance of breast-feeding to the well-being of both infant and mother. The late Sir Frederick Truby King, founder and director of that organization, emphasized that breast-feeding, at any rate during the earlier post-partum period, stimulated the physiological contraction of the uterus. May it not be that failure to maintain breast-feeding is one of the causes of subinvolution and subsequent malposition of a flabby uterus? It is at least logical to expect that it has some reflex relationship to the involutionary changes in the pelvis that follow on the termination of pregnancy.

Again, Truby King also taught with great success that one of the most potent factors in maintaining an adequate supply of breast milk was the complete emptying of the breast at each feed; and for this reason he advocated feeding the baby at one breast only at one feed, and at the other breast at the next feed. It was the complete emptying rather than frequent suckling that was the effective factor; and to ensure complete emptying of the breast the infant must not be fed too often. King also taught the importance of sufficient fluid being taken by the mother.

May I pay a tribute here to Sir Frederick Truby King, who worked most of his life in New Zealand for the better health of women and children, often against bitter opposition and apathy. Nothing would have better pleased him than to read Dr. Spence's paper in the *B.M.J.*—I am, etc.,

Birmingham, Oct. 12.

E. H. WILKINS, M.B., D.P.H.

"Ether Convulsions"

SIR.—We have read the case reports of Dr. S. Taylor and Dr. V. Goldman and the interpretation they place on them (*Journal*, October 8, p. 744). We are of the opinion that the factor of CO₂ accumulation, which they have not considered, is a vital one.

Very little attention has been paid to the valuable observations of Dr. K. B. Pinson, who has reported the largest series of these cases, and we believe it well worth while to bring to light again some extracts from his original paper (*British Medical Journal*, 1927, 1, 956).

"... I have come to regard the convulsion as largely the outcome of the extensive action of the CO_2 in patients who are sensitive to this naturally, or by reason of toxæmia, pyrexia, and so on. . . . Treatment based on this assumption has so far been successful. It is directed to the riddance of excess CO_2 , and must be prompt. Luckily some moments' warning is given of the impending seizure by twitching of the eyelids and mouth, jerkiness of the breathing, especially inspiration, or some strange movement or sound, and so the essential thing can be accomplished—the immediate removal of all coverings from the face before the convulsions have set in. . . . Any obstruction must be completely relieved. . . . In this way the CO_2 will diminish as much as possible by natural means."

It is also a little disappointing to realize that the experiment in which one of us (M. D. N.) was half killed by the other was made to no purpose. In this experiment (*British Medical Journal*, 1937, 2, 995) the subject inhaled an 80/20 per cent. helium-oxygen mixture to which CO_2 and oxygen were continuously added (the helium being used to diminish exhaustion caused by the hyperpnoea). Muscular twitchings were first noticed about the eyes, and these passed on to generalized convulsions, which subsided after a few breaths of air.

In fit normal subjects low concentrations of CO_2 have a stimulating action, and it may not be until a 10 per cent. concentration is exceeded that toxic effects become obvious. The susceptibility of different people to CO_2 , however, varies considerably, and a concentration which is stimulating for a time to one person may be toxic to another—as shown by respiratory and circulatory depression as well as by muscular spasms.

We now suggest that the following sequence of events occurs in the vast majority of cases of convulsions during anaesthesia. The usual type of patient is a toxic individual who is already acidotic. Then follows some further increase in CO_2 , caused by the addition of that gas, by the use of rebreathing, by the presence of respiratory obstruction, or by the decreased pulmonary ventilation of deep anaesthesia or other abnormal condition. No matter by what means the CO_2 is raised, a toxic concentration is reached in that particular individual, and this precipitates the convulsions. Respiratory obstruction, if evident in such a case, has in our experience been followed by shallow jerky breathing and not by the hyperpnoea postulated by Drs. Taylor and Goldman.

The anti-convulsant properties of the barbiturates are well known, but our aim should be to prevent the onset of convulsions. Some factors, such as the type of patient, are obviously beyond our control, but every effort should be made to eliminate the one factor which is under our control—namely, a CO_2 pile-up. If in spite of all precautions muscular twitchings are observed, Dr. Pinson's advice should be followed and every effort made to lower the alveolar CO_2 before injecting a barbiturate.

We feel that the term "ether" convulsions is a misnomer; if Drs. Taylor and Goldman still doubt that excess CO_2 is an aetiological factor, we will do our best to produce convulsions by means of CO_2 in either of them, while the other acts as observer. As presumably neither of them is acidotic, a relatively high concentration will probably be necessary, and we can offer no guarantee that more than one of them will live to tell the tale. —We are, etc.,

M. D. NOSWORTHY.

R. F. WOOLMER.

London, Oct. 11.

SIR,—The "provisional theory" offered by Drs. S. Taylor and V. Goldman in the *Journal* of October 8 (p. 744) is an over-simplification not justified by the

facts. These authors suggest that an essential element in the production of ether convulsions is alkalaemia resulting from the loss of CO_2 . This is not a new suggestion, and it has less to commend it than its opposite—namely, that ether convulsions are caused or precipitated, other factors being appropriate, or by the accumulation of CO_2 .

At a recent "anaesthesia staff meeting" at Wisconsin Waters¹ stated that "convulsions during anaesthesia have been, in well over 90 per cent. of the cases, connected with an excess of CO_2 in the respired atmosphere." The same meeting discussed two cases of ether convulsions occurring in patients in whom acidosis had been produced by the administration of ammonium mandelate. They were successfully treated by intravenous injection of alkali. It may be significant that the majority of cases occur under conditions in which there may be defective removal of CO_2 from the respired gases, whilst the concentration of oxygen is maintained at a high level. Campbell² showed in 1925 that the CO_2 content of the tissues is greatly increased by breathing an atmosphere containing as little as 40 per cent. oxygen.

According to Campbell,³ the respiring of oxygen at several atmospheres' pressure may lead to convulsions because oxyhaemoglobin is not reduced, sufficient oxygen for the needs of the tissues being carried in the plasma under these conditions. Oxyhaemoglobin assists the removal of CO_2 from the tissues less efficiently than does reduced haemoglobin; the CO_2 pressure within the cells rises and convulsions follow. In view of the strong correlation between CO_2 excess and ether convulsions it is possible that some rather similar mechanism will account for the occurrence of this grave emergency. Any combination of factors leading to a disturbance of the acid-base balance of the blood towards the acid side may prepare conditions for what Waters refers to as the "so-called trigger effect of CO_2 " in inducing a convulsive seizure.

It should be remembered, however, that (though strongly suggested by clinical observations, the " CO_2 -excess hypothesis" has very little more exact experimental evidence than the " CO_2 -lack hypothesis." Lundy⁴ gives a list of thirty-three aetiological factors which have been invoked in the literature, some of them mutually exclusive. The only prospect of disentangling the confusion which has arisen lies not in the championing of rival hypotheses but in the provision of a body of experimental data which can be analysed in the usual inductive manner.—I am, etc.,

C. L. G. PRATT.

A Strict Vegetarian Diet

SIR,—May I repeat the statement made in my paper (August 20, p. 417) that the determinations of total nitrogen and urea were made for me by a chemical pathologist of distinction, that two samples were collected at intervals of some weeks and the results closely agreed and that the pathologist, in his own experience, had never come across a lower total nitrogen value.

The oxygen consumption of the boy indicated a caloric value of the diet bigger than that reported, and I have told the father that his diet records are not believed. I have not been able to shake the evidences either of the boy or of his father, a man of high character, who welcomes further scientific observation at his home.—I am, etc.,

LEONARD HILL.

Adult Scurvy

SIR,—I should like to make a brief comment on a case of adult scurvy described by Dr. G. H. Jennings and Surgeon Lieutenant A. J. Glazebrook in the *Journal* of October 15 (p. 784), since I feel the impression given is slightly misleading. The report on the bone marrow quoted is that sent to the ward at the time of the patient's admission; since then I have had the opportunity of examining marrow films from a large number of cases of Addisonian pernicious anaemia. The primary erythroblasts in the case described are much more mature than those seen characteristically in pernicious anaemia. I would no longer say that the film was compatible with such a diagnosis. In fact it is now used for teaching purposes as an example of megalocytic anaemia where the marrow picture should have enabled us to state that the case was definitely not one of the Addisonian type.

I can only regret that my ignorance in the first place may have confused the issue.—I am, etc.,

London, W., Oct. 17.

JANET M. VAUGHAN.

Aperients and Sulphanilamide

SIR,—In your issue of June 25 (p. 1392) a letter from Dr. Harry Roberts appears concerning the administration of sulphanilamide with saline aperients. As it is generally believed that the concomitant administration of sulphur-containing purgative drugs, such as magnesium sulphate, with the drugs of the sulphonamide group is not devoid of danger, I feel that the following case would be of particular interest as magnesium sulphate was given continuously with maximum doses of carboxy-sulphonamide-chrysoidine (rubiazol) over a period of ten days without any toxic manifestations occurring.

A boy of 8 years was admitted to Wimbledon Hospital on September 7, 1938, his mother having noticed discoloration of the urine and oedema of the face for four days.

On examination the child was found to have enlarged tonsils (he had suffered from an attack of tonsillitis three weeks previously); there was slight oedema of the face; and his blood pressure was 150/90. The physical signs in the chest were diffuse tubular breathing, rhonchi, and crepitations. Pathological findings were as follows: The urine was acid and contained 6 per cent. of albumin (Esbach), many pus cells and red cells, and casts. Culture gave a strong growth of *B. coli* and enterococci. A throat swab showed a mixed culture of *Strep. viridans* and *Staph. aureus*. The blood culture was sterile. The blood urea was 46 mg. per cent.

He was nursed on the balcony during the day-time, sitting up in bed. Fluids were restricted to 1½ pints of glucose and orangeade per day. An electric pad was applied to his loins and the following drugs were given: pot. cit., 20 grains four-hourly; mag. sulph., 1 drachm; mane; linctus sedativus, 1 drachm, nocte; mist. ammon. carb., 1 drachm three times daily. On the second night he was very restless and "chesty," and his temperature rose to 103.6° F. and his respirations to 40 a minute. At 10 p.m. he had a rigor. Two tablets of rubiazol were given at once and he was put on one tablet (3 grains) four-hourly. The next evening his temperature was 102° F., but his respiration rate rose to 60 a minute. Continuous nasal oxygen was given throughout the night. The following evening, although his temperature was still up to 103° F., he was very much better and respirations were quite easy—30 a minute. His temperature became normal within five days. The oedema of face had disappeared. Each day his urine was tested and the percentage of albumin steadily diminished, as also did the pus cells and red cells. The volume passed was about 13 ounces in twenty-four hours. All this time his skin was acting well and his bowels opened regularly each day with half a drachm of magnesium sulphate in the mornings.

On the tenth day there was a faint trace of albumin in the urine, but no red cells or pus cells. Culture was sterile. There was no oedema, and the signs in the chest were very slight. All drugs were stopped, including rubiazol. He was started on a light diet (excluding meat, eggs, and cheese) with as much fluids as he could drink. A good diuresis was produced. Fluid intake was measured against the urinary output for a few days—for example:

11th day :	fluid intake	50 ounces,	urinary output	14 ounces
12th "	"	35 "	"	17 "
13th "	"	40 "	"	14 "
14th "	"	37 "	"	29 "

He was allowed up on the fifteenth day of his illness and made an uneventful recovery.

It is clear that in the above case a considerable amount of magnesium sulphate was administered at the same time as full doses of carboxy-sulphonamide-chrysoidine, resulting in complete recovery without any signs of toxicity occurring at any time. Although the mechanism of the action of the drugs of the sulphonamide group is not at present fully explained, it would appear that the action of the red compounds (such as carboxy-sulphonamide-chrysoidine) in the organism is quite different from the white substances (para-amino-benzenesulphonamide). It has previously been shown by Young, Snodgrass, and Anderson that the red substances are less toxic than the white, but so far as I am aware this is the first case reported where a sulphur-containing compound has been administered with a sulphanilamide product without any toxic signs being observed.

It would be interesting to hear of any similar cases, as clearly one case of this nature proves nothing in itself. I have to thank Dr. E. B. Rayner for permission to publish this report.—I am, etc.,

London, S.E.1, Oct. 7.

PHILIP GRIMALDI.

Overdosage of Prominal

SIR,—In view of the absence of clinical reports concerning prominal poisoning I have thought it advisable to record the following case. (Prominal is *N*-methylethylphenylmalonylurea.)

The patient, a married woman of 29 who had suffered from epilepsy since the age of 18, had been taking three or four prominal tablets a day for some years, the fits on this dosage occurring once or twice weekly. On September 5, 1938, after obtaining possession of a box containing fifty 3-grain tablets, she settled down in bed with a novel and swallowed the tablets one after the other until the box was emptied. Although it was certain that she had swallowed this number I was not called to see her until September 10, five days later; she was then in a semi-stuporous condition. When spoken to sharply in a loud voice she replied in a vague way; her breathing was very shallow, her colour was good, and her pulse and temperature normal. Her pupils were rather large and reacted slowly to light. This condition slowly disappeared, and by September 16—that is, eleven days after the ingestion of the drug—the patient was normal. Her relatives assured me that she had missed no meals, and that her hours of sleeping and waking had not been altered. In addition she had been given her usual aperient each night, and had been sufficiently conscious to be supported to the bathroom daily, although she had been unable to attend to her toilet. An interesting point in connexion with this case is that the patient developed a slight attack on the morning of the eleventh day, and that during that period she would have taken almost as many tablets as she consumed in the single dose. On the twelfth day she had two attacks; she then resumed her usual dose, and twenty-four days after recommencing the prominal she had not had an attack.

I have been unable to find a report of a similar case of overdosage with prominal, but it is of interest to compare this with the case of luminal poisoning reported

by J. P. Stewart and W. Willcox (*Lancet*, 1934, 1, 502), in which recovery occurred after the ingestion of 100 grains of luminal, although the symptoms were much more severe than those displayed by my patient. The toxicity of prominal is stated by the makers to be 30 per cent. lower than that of luminal. This case illustrates very clearly the strong sedative effect without the hypnotic action.—I am, etc.,

Blackburn, Lancs, Oct. 9.

D. KELLEHER.

Palpation of the Trachea

SIR,—Although it is obvious that determination of the position of the trachea in the lower part of the neck only justifies a surmise as to the position of the upper mediastinum, more and more attention has been paid to this physical sign in recent years. Hence I make bold to describe the following method, which I have found very useful in eliciting the physical sign and in demonstrating it to students.

The observer's thumb is placed on the patient's neck as low down as possible between the sternal head of the right sterno-cleido-mastoid muscle and the trachea, while the fingers are placed on the belly of the clavicular head of the left sterno-cleido-mastoid just above the clavicle. An attempt is then made to grasp the trachea between the finger and thumb without displacing the structures of the neck. The same thing is then attempted on the other side, this time with the fingers on the trachea between it and the left sterno-cleido-mastoid and the thumb on the belly of the right sterno-cleido-mastoid. If, as is usual, the trachea lies in the midline, then it is impossible to grasp this organ without grossly displacing the structures of the neck by either grip, but the slightest displacement to either side brings the trachea under the belly of the sterno-cleido-mastoid on that side and allows the former to be easily felt by the grip described above.

Treatment of Infections of the Hand

SIR,—I have read with interest Mr. Norman Lake's three articles on infections of the hand in your issues of October 1, October 8, and October 15, and must confess to some sense of disappointment as each succeeding instalment failed to reveal a rational treatment. Some reference was made to arm baths; I had hoped it would be a condemnatory reference, but it seems that soakage in aqueous solutions is still to be tolerated, with its sequelae of unhealthy, swollen, drainage-damming granulations; secondary infection; and subsequent stiffness.

No mention is made of the virtue of infrequent dressing on the Winnet-Orr principle: that is, after adequate incision a large quantity of vaseline is applied on gauze and the dressing left for five to seven days. With this treatment artificial drainage, which Mr. Lake rightly condemns, is unnecessary. The advantages of this method are numerous:

1. The dressing can be painlessly removed without disturbing healthy granulations.

2. Vaseline is, biologically speaking, non-nutrient to bacteria, as it cannot be broken down and does not form a suitable medium for their growth; it also forms a physical barrier to their entry; any bacteria in the wound can be dealt with by tissue defence.

3. Movement short of pain is always encouraged. This promotes a flow of discharge into the vaseline which prevents crust formation, and return to normal is accelerated. Rigid splints are unnecessary.

4. The hospitals whose out-patient departments favour the vaseline treatment of hand sepsis can show a nil return for such cases admitted to the wards; the reverse is the rule in "arm-bath" clinics.

5. Economy of out-patient staff time and hospital material.

6. Patient returned to work with a useful hand in minimum time.

7. Re-education in physical treatment departments is hardly ever necessary.

8. And greatest of all—an economy in pain.

Longtown, Cumberland, Oct. 15.

R. RUTHERFORD.

Diagnosis of Whooping-cough

SIR,—In reply to Dr. A. Gordon Moore's letter (*Journal*, October 1, p. 722), in which he regrets that I was only able to devote a few lines to agglutination tests as a diagnostic aid in whooping-cough, may I enlarge on my findings.

Agglutinins were first demonstrated by Bordet and Gengou in 1907, but they were very guarded in their conclusions and stated that the power of agglutination in convalescent sera was very weak, having found that many sera giving a strong complement-fixation test had practically no agglutinating power; and they believed that the bacilli become so modified when grown on artificial medium that they are incapable of reacting with convalescent sera. In view of this all strains used in my tests were grown for twenty-four or forty-eight hours on Bordet medium containing 50 per cent. horse blood, which maintains the *Haemophilus pertussis* in its smooth phase.

An effort was made to demonstrate agglutinins in the blood of cases of whooping-cough from the second week onwards, but with one exception all were completely negative. The one successful case agglutinated to a titre of 1/128 in two hours' time in two series of dilutions, one of which was placed in a water-bath at 36°C. and the other in the incubator at 37°C. This serum was from a patient in the eighth week of illness, and the complement-fixation test was strongly positive. Various other sera giving positive complement-fixation tests were put up at the same time in duplicate, as above, using the same strain of bacillus, but results were completely negative. The dilution of organisms in all cases was approximately 2,000 million per c.cm. In all, fifty different sera were tested, most of which gave strongly positive complement-fixation tests, and as they all failed to show agglutination at any time during twenty-four hours the conclusion came to was that the agglutination test was unreliable and useless as a method of diagnosis.

A. B. DONALD.

Tomography in the Vertical Position

SIR,—Drs. J. B. McDougall and J. H. Crawford, who in their paper on tomography (*Journal*, October 15, p. 782) were kind enough to refer to my work, stated that it is claimed (my italics) that by vertical tomography the upper limit of a pleural effusion or the line of a fluid level in a cavity is not obliterated. It would have been more correct to have said that by working in the vertical position fluid levels can unquestionably be shown when ever fluid is present. Such has been my experience in every case of this type that I have examined. Surely the limitation of the original apparatus devised was the excuse for departing from the more usual practice of

radiographing the chest and other air-containing cavities such as the nasal sinuses in the upright position. The obvious advantages of the vertical technique hold for tomography no less than for simple radiography.—I am, etc.,

Croydon, Oct. 17.

CHARLES COLYER.

Admission of Foreign Doctors

SIR.—In the debate on Government foreign policy last night Mr. Richard Acland, member for Barnstaple, made the following pronouncement (*Hansard*, October 5, col. 389):

"I would ask the doctors of this country, who were rather forward in pressing hon. members of this House to forbid the influx even of as few as fifty alien doctors per year, to remember that while they can pursue their practice in peace many of their fellow combatants in the battle of humanity against disease will be driven into bankruptcy and into suicide in Prague, and I invite them or the Government to suggest a scheme whereby this country might take in 500 doctors a year from Czechoslovakia; not necessarily to enter private practice, but to try to find some research work which they can do here for the sake of humanity."

It being the last night of the special session dealing with the international crisis the House was crowded beyond precedent and I could find a seat only behind the bar, which while actually within the Chamber is technically outside for purposes of debate; consequently I was unable to make any protest, and the proposition passed unchallenged.

The specious pretext that a large number of foreign doctors could be advantageously admitted to this country, "not necessarily to enter private practice but to try to find some research work," has been used again and again and ought, I think, to be definitely debunked. The great majority of the proposed annual entry of 500 Czech doctors would be persons of middle or mature age without any previous experience of research, and to claim that they could forthwith embark upon that most difficult branch of medical work in an alien country with an alien language in a peculiarly alien atmosphere is surely the purest claptrap. Mr. Acland is a barrister, and in the earlier part of his speech he mentioned that lawyers as well as doctors are being persecuted in Prague, but there was no suggestion in his speech that the legal profession in this country should open their doors to their harassed colleagues in Prague.

In an answer to a Parliamentary question (*Hansard*, March 7, 1938) it was stated that "during the year 1937 extensions of stay in this country were granted in 813 cases of professional men and women who had arrived during the last three or four years," of whom 181 were doctors, 66 dentists, and only 12 lawyers! Nearly "300 research workers," whose occupation was not otherwise specified, were retained. The medical profession ought not to be, and in fact is not, indifferent to the ghastly sufferings of so many of our professional brethren in Central Europe, but serious thought should be given to the practicability of the remedies proposed to relieve them. Some two months ago I asked a question in the House

(*Hansard*, July 25, cols. 2734 and 2745) worded as follows: "Whether the Secretary of State for the Colonies is aware that, whereas the number of persons per qualified doctor in Great Britain is approximately 1,000, in some parts of the British Colonies (to be carefully distinguished from the Dominions) the proportion is as high as 100,000; and whether, in these circumstances, he has under consideration any plans or increasing the personnel of the Colonial Medical Service." And I suggested that it was in this field that medical refugees from Central Europe might find sanctuary.

For some years now I have been interested in the medical conditions prevailing in East Africa, and I have

received a large mass of information, based upon authoritative local knowledge, which indicates that there is a crying need for qualified medical practitioners in that vast area of the British rule. The refugees would be called upon to practise medicine, for which their experience would obviously fit them better than to undertake research. The Colonial Secretary's answer was entirely discouraging, but surely mine is a more promising solution than that proposed by Mr. Acland.—I am, etc.,

House of Commons, Oct. 6.

E. GRAHAM-LITTLE.

Obituary

JOSEPH POWER, M.B.

Late Chairman of the Irish Medical Committee

The death of Dr. Joseph Power, formerly medical officer of the Ardfinnan dispensary district, Co. Tipperary, occurred after a long and painful illness at his residence, Knockaun House, Cappagh, Co. Waterford, on September 25. He was 69 years of age. Born near Dungarvan, Co. Waterford, and educated at Rockwell College, Cashel, and Trinity College, Dublin, Power qualified as M.B., B.Ch., and B.A.O. of Dublin University in 1893. During his course in Trinity College he won a Stewart Scholarship in Anatomy and Institutes of Medicine, and he also gained reputation as an athlete. He practised for a short time in Dungarvan, and in the East End of London, before being appointed to the dispensary district of Ardfinnan, where the rest of his professional life was spent. He retired from practice on account of ill-health some five years ago, and devoted his time to farming, in which he had always been much interested.

Power was a capable and conscientious country doctor, but his interests were never bounded by his purely professional duties. In particular he was interested in medico-political affairs, and was an active worker in the British Medical Association, of which he had been a member for thirty years. He was chosen as one of its representatives on the Conjoint Committee of the British Medical Association and the Irish Medical Association, which was formed in 1911 to deal with problems connected with national health insurance. In the business of that committee and of its successor, the Irish Medical Committee, he made his mark as one of the most practical and clear-minded members. In 1915 he was elected vice-chairman of the Irish Medical Committee, and in 1922, on the separation of Northern Ireland from the Irish Free State, he became chairman. He retained this position until the dissolution of the committee some three years ago. As chairman he conducted the business briskly, fairly, and firmly. He kept the essential points before a meeting, and was stern in preventing any wandering into non-essentials. He showed the same qualities when acting as spokesman for the profession in interviews with Ministers or Government Departments, and while he was uncompromising on matters of principle his sense of fairness rendered him accommodating in matters of detail. It was mainly due to his activities in association with those of the late Dr. Thomas Hennessy, Irish Medical Secretary of the British Medical Association, that the present system of certification of insured persons was agreed on with the Insurance Commissioners. He was president of the South-Eastern of Ireland Branch of the British Medical Association in 1912, deputy representative in the Representative Body

from 1913 to 1918, and representative in 1919, 1920, and 1921. He was a member of the Irish Committee from 1923 to 1934.

Dr. Power had a great love of country life and its occupations and pastimes—farming, shooting, fishing—and his knowledge of botany and the wild life of the fields made him a delightful companion on a country walk. He was widely read in general literature, and his comments on men and affairs were shrewd and entertaining. An upright and honourable man, and a good friend, he was trusted and respected both by his fellow-practitioners and by his patients, and to both he performed his duty in full measure. He is survived by his wife, three daughters, and two sons, of whom one is a member of the medical profession.

J. STODDART BARR, M.B., F.R.A.C.S.

Dr. John Stoddart Barr, who had only comparatively recently returned to Scotland after long residence in Hobart, Tasmania, died suddenly at Troon, Ayrshire, on September 14. He was born in Glasgow in 1878, the second son of the eminent aurist, Dr. Thomas Barr—a former lecturer in otology at the University—and began his medical studies at Glasgow University in 1896. In 1901 he graduated M.B., Ch.B., and became house-physician to Dr. James Finlayson, and, later, house-surgeon to Sir Hector C. Cameron in the Western Infirmary, Glasgow. He had decided, early in his career, to devote himself to the practice of diseases of the ear, nose, and throat, and with that end in view spent a year in postgraduate work in Vienna, afterwards studying in Zürich and London, and with Sir William Milligan in Manchester. In 1905 he was appointed assistant surgeon to the Glasgow Ear, Nose, and Throat Hospital, and in 1908 assistant dispensary surgeon for diseases of the ear to the Western Infirmary, Glasgow. In 1912 he developed a grave illness, which resulted in the following year in the loss of a lower limb and subsequent minor operations. His long convalescence was spent in the South of France and Cornwall. Finally, he decided for health's sake to make his home in Hobart.

Before leaving for Tasmania a high medical authority had strongly counselled him never again to engage in practice. Barr, however, was built in heroic mould and was not one to yield to the buffetings of fate without a struggle; soon after settling in Hobart he resumed his work and built up a considerable practice. In 1927 he became a Fellow of the Royal Australasian College of Surgeons. At the Annual Meeting of the British Medical Association in Belfast in 1909 he was Secretary of the Section of Laryngology, and a Vice-President of that Section at the Annual Meeting in Melbourne in 1935. When on a visit to this country he was the bearer of the mallet from the Tasmanian Branch when the new B.M.A. House, Tavistock Square, was opened in 1925. He was joint-author of the sections on diseases of the ear and throat in Choyce's *System of Surgery* (1913), and of the *Manual of Diseases of the Ear* (fourth edition, 1909). For a short time he held the rank of captain in the R.A.M.C.T. His death came as a surprise and great shock to his family and friends; indeed, he had intended to leave shortly for Cyprus, with the possibility of residing there.

A former colleague writes:

Barr's tragic ordeal, occurring in his early and such vital years, cruelly restricted his career. He was a skillful and confident operator, the outcome of natural endowments of a high order coupled with careful and assiduous

training. Investigation appealed to him. I well remember associating with him at the outset of his career when he made certain experimental researches on the cadaver. It is not improbable that he would have engaged in further research but for the incidence of his grave illness. For one of Barr's athletic tendency—he had been a golfer, tennis-player, swimmer, and skater—his affliction must have been extremely hard to bear, yet I never once heard him complain. He was a man of fine feelings, eminently sympathetic to the poor and oppressed, a whole-hearted champion of liberty, a staunch and loyal friend; possessed of a singular charm of manner with a keen sense of humour, he radiated good fellowship and shone in the social circle. Barr did not neglect the cultural side of life; he was interested in zoology, and was a lover of pictures, exceptionally fond of verse, and the possessor of a well-trained baritone voice. To his intimate circle he has left a heroic example of unshakable optimism, stout endurance, and persistent endeavour in the face of a tragic happening which none but one possessed of the finest qualities of heart and mind could hope to bequeath.

THE LATE ALEXANDER MACPHAIL

Sir Weldon Dalrymple-Champneys, Bt., writes:

May I be permitted as an old friend and colleague of the late Professor Alexander Macphail to add a short appreciation to the obituary notice in your issue of September 10. I first met Macphail in 1912, when he had just become lecturer in anatomy at St. Bartholomew's Hospital and I had not yet begun studying medicine, but it was not until 1929 that I came to know him well. In that year I began to share a room with him in the Ministry of Health, and continued to do so until his death. A more delightful colleague and companion cannot be imagined. In him I found that rare combination of refinement and gentleness with moral courage and on occasion righteous indignation, the whole illumined by a strong sense of humour. His religion was real and deep but never obtrusive, and it was impossible to imagine him doing anything which savoured in the least of meanness or self-seeking. From his father, the well-known Gaelic poet of Mull, he had inherited a love of nature and artistic talents, which showed themselves chiefly in the delightful watercolours, some of which he showed every year at the Ministry of Health's Art Exhibition. For some years he had suffered greatly from attacks of bronchitis, which became more and more frequent, necessitating weary periods in bed, but he was always cheerful and uncomplaining and far more interested in other people's troubles than in his own. His death leaves a real gap in the lives of all who knew him well and to whom he was the personification of a Christian gentleman.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred at a Congregation held on October 13:

D.M.—H. S. Brodribb.
B.M.—A. W. Frankland.

The Nuffield Foundation

A year ago Lord Nuffield, in addition to his previous endowment of two millions for the widening of the scope of the medical school at Oxford, gave a further £200,000 for the erection of buildings at hospitals associated with the medical research scheme. In his oration (which was a valedictory

after three years of office) in Convocation on October 5 the retiring Vice-Chancellor, Mr. A. D. Lindsay, stated that out of this fund there had so far been expended some £75,000 on buildings completed or in construction—principally new surgical and gynaecological wards at Radcliffe Infirmary and maternity home extensions, which absorbed over £60,000, also on an extension of the pay-bed block and x-ray theatre.

The last of the four basic clinical professorships in the Nuffield medical school, as already announced, has been filled by the appointment of Professor L. J. Witts as professor of clinical medicine, and the Vice-Chancellor stated that all the clinical professors are now working full time in their departments. He warned any who might cherish such an expectation that it must not be supposed that sensational discoveries would rapidly ensue or, indeed, should be sought. The vast machine of research must first be welded into a unity. This process, he said, was going apace, and had been helped during the year by the creation of a fluid research fund from which would be financed those promising research projects which emerged from time to time, now in one department and now in another. Such projects, born of happy inspiration or lucky accident, could not be foreseen or provided for in the routine departmental budgets, and so the fund would be open equally to all departments of the school.

Another Oxford development, again made possible by Lord Nuffield, is the foundation of three clinical assistantships tenable in the clinical departments of the medical school and three demonstratorships in the pre-clinical departments by graduates of universities in Australia, New Zealand, and South Africa. The tenure of each post is three years, after which the holders will be expected to return to teaching or research posts in the Dominions. The idea is that Dominions remote from the great centres of research will be enabled to participate in the work of the Oxford school. Provision is also made for the appointment at frequent intervals of a visiting professor to tour the Dominions with a view to giving and receiving information.

A tribute was paid by the Vice-Chancellor to Dr. Simon Flexner, whose appointment as George Eastman Visiting Professor has just terminated. His presence in Oxford, said Mr. Lindsay, had been of incalculable advantage to the medical school. His accessibility and his powers of lucid exposition endowed the new school at its birth with the benefits of the experience of a lifetime devoted to similar research.

New Physiology Laboratory

Among other developments at Oxford mentioned by the Vice-Chancellor is the planning of a new physiology-laboratory to replace the present building, which was erected more than fifty years ago. Hitherto the state of overcrowding in a building intended to accommodate forty students and having to provide for four or five times that number has entailed the repetition of many lectures and demonstrations. The new laboratory will include library and common rooms to be shared by the department of biochemistry, and will cost £120,000.

A second May readership in medicine has been established on a temporary basis for three years, and has been filled by the appointment of a reader who will help to bridge the gap in the teaching of physiology and clinical medicine by conducting an extended course in general pathology. The tenure of Dr. A. M. Cooke, who was appointed May reader in 1933, has been extended for a similar period, and, when the two readerships become vacant simultaneously in 1941 the whole position will be reconsidered.

UNIVERSITY OF CAMBRIDGE

At a Congregation on October 15 the following medical degrees were conferred:

M.D.—C. G. Parsons, *H. Smith.
M.B., B.Chir.—C. W. Hutt, *K. W. Donald, T. A. W. Edwards, W. E. D. Moore, J. S. Heller, G. M. Little, J. P. Henry, E. A. Evans, A. G. Marshall.
M.B.—J. A. Falk.
B.Chir.—C. H. M. Gimlette.

* By proxy.

Pinsent-Darwin Studentship in Mental Pathology

The managers give notice that an election to the above studentship will be made in January, 1939. The studentship is of the annual value of not less than £225, and is tenable for three years. The student must engage in original research into any problem having a bearing on mental defects, diseases, or disorders, but may carry on educational or other work concurrently. Applications for appointment to the studentship should be sent before December 1 to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cam-

bridge. Applicants should state their age and qualifications and the general nature of the research that they wish to undertake. No testimonials are required, but applicants should give the names of not more than three referees.

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—Part II: G. Q. Chance, W. J. Craig, T. Fichardt, R. L. Mansi, A. M. Mansour, C. G. Talwalkar.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—Parts II and III: J. Beech, E. G. Crookes, N. W. Jones, J. S. Lindsay, W. J. Wilson.

UNIVERSITY OF GLASGOW

At a Congregation held on October 15 the following degrees were conferred:

M.D.—J. I. Russell, †C. Glen, †I. MacKay.
M.B., Ch.B.—J. Walker, †N. G. B. McLeitchie, †A. Brown, †Elizabeth B. S. Scobbie, †T. Gibson, †Janet R. Mowat, †R. T. S. Gunn, †A. Macfarlane, W. C. Alford, H. M. Archibald, G. W. Armour, W. Auld, W. Bain, Margaret R. Barr, G. D. S. Beechey, A. M. Brannan, J. Brown, Margaret A. F. Burton, D. C. Caldwell, C. Cameron, D. Christison, J. Y. Clark, Marion A. Crawford, R. C. Cunningham, Margaret M. B. Curley, Ellen Cush, I. MacK. Davidson, J. S. Dawson, E. C. Easson, Jay Fairweather, W. Ferguson, J. D. Frame, J. R. Gallie, J. Garden, J. L. Gilloran, J. Glen, M. Goldin, R. Good, T. T. Graham, A. Granat, Helen W. Greenles, G. A. Guthrie, A. J. Haddow, A. R. Harper, L. G. Harper, A. W. Harrington, T. Hart, F. J. Hebbert, I. B. Hopkins, F. Iskander, A. S. Johnston, E. de C. Kite, Mary MacT. Leitch, J. B. McCaullum, I. M. McCully, D. Macdonald, A. McDougall, J. D. McFadyen, Jean M. McGill, A. W. McHaffie, I. McIndewar, J. R. Macintyre, I. C. K. Mackenzie, H. McKeown, W. MacK. McLennan, Julia M. Middleton, W. Mullen, R. L. Orchardson, G. D. Park, Mary R. Paterson, D. Paton, R. Provan, A. J. G. Pullar, D. Purdie, C. McK. Ramage, R. Rankin, I. Rannie, A. G. Reid, J. Reid, R. V. Rhoda, J. H. Rosengard, Margaret C. G. Russell, G. H. Scouler, M. Shaw, D. R. Sloan, James Smith, John Smith, L. Steingold, J. H. Stirrat, W. B. Summers, Anna J. Sutherland, J. A. Sutherland, A. M. Tait, R. D. Taylor, Barbara S. Thomson, K. R. Thornton, W. V. Wallace, N. Waters, J. Wishart, Shanna B. Wright, D. Yellowlees, A. Young, I. M. Young.
B.Sc. (Pure Science).—Etheldreda Cadas, M.B., Ch.B.

* With high commendation. † With commendation. ‡ With honours.

James Walker gained the Brunton Memorial Prize, awarded to the most distinguished graduate in medicine for the year 1938.

The West of Scotland R.A.M.C. Memorial Prize was awarded to Janet R. Mowat and John F. B. Wyper (equal) as the candidates who obtained the highest aggregate marks in surgery, medicine, and midwifery in the final M.B., Ch.B. examinations held during 1938.

The Macewen Medal in Surgery was awarded to Alexander Macfarlane as the candidate who obtained the highest aggregate marks in surgery at the final M.B., Ch.B. examinations held during 1938.

The Stockman Medal was awarded to Elizabeth B. S. Scobbie as the candidate who obtained the highest aggregate of marks in the professional examinations in materia medica and therapeutics and medicine (written, oral, and clinical), excluding paediatrics, in 1938.

The Captain H. S. Ranken, V.C., Memorial Prize was awarded to James W. Chambers as the candidate who obtained the highest marks in pathology in the professional examinations in 1938.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Professor J. B. S. Haldane, F.R.S., will deliver the 1938 Lloyd Roberts Lecture, on "Some Problems of Human Congenital Disease," at the College, Pall Mall East, S.W., on Thursday, November 17, at 5 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Council of the Royal College of Surgeons of England was held on October 13 with the President, Mr. Hugh Lett, in the chair.

Mr. Frank Batley was admitted as a Macloghlin Scholar. Sir Alfred Webb-Johnson stated that he had been asked by an anonymous donor to offer the College a gift of five hundred guineas for the completion of some special work. The Council accepted this munificent gift with very grateful thanks.

The Council stated that it was prepared to hold a Primary Examination for the Fellowship in Australasia every three years, the next examination to be in February, 1941.

The general annual report and the scientific report of the Council were approved.

It was reported that the office and secretariat of the Imperial Cancer Research Fund were now established at the College.

Counsel's opinion stating that the existing charters do not give the College power to grant a higher diploma in dental surgery was before the Council.

The Council accepted with grateful thanks a bust of John Whitaker Hulke, President in 1893 and 1894, presented by the Middlesex Hospital, and a bust of Thomas Wormald, President in 1865, presented by the Wormald family.

Diplomas

A Diploma of Fellowship was granted to Robert Officer.

Diplomas of Membership were granted to Phoebe Charlton, Abraham Caplin, and Hugh Stott.

Diplomas in Child Health were granted, jointly with the Royal College of Physicians of London, to the following candidates:

Khairunnisa B. Ahmed, A. M. Clark, J. H. Colebatch, S. D. M. Court, A. G. Denison, M. L. Edwards, Irene K. Falk, Mima M. Gemmell, S. M. Ghosal, K. N. Gour, Alice M. Headwards, R. S. Illingworth, F. D. M. Livingstone, S. Mackenzie, N. S. Mair, Queenie I. E. May, A. B. Milligan, Anasuya Mundle, Margaret I. Neal, M. N. Pai, Helen J. L. Robertson, A. T. Roden, A. V. S. Sarma, S. S. Sawaf, M. Seraj-ul-Haque, Florence Stephen, Shirley M. Taylor, Achamma Thomas, Mary A. Thomas, M. Trivedi, F. Walt, C. B. M. Warren, R. G. Wilbond, Elsa P. Woodrow.

The following hospital was recognized for the six months' surgical practice required for the Final Fellowship:

Harrogate and District General Hospital, house-surgeon, till July 31, 1939.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

The progressive reduction in the incidence of acute poliomyelitis observed during the previous three weeks in England and Wales has not been maintained during the week under review, the notifications having risen from 56 to 65, and in London from 3 to 6. In Scotland notifications rose from 5 to 8. The counties mainly affected were: Essex 9 (4), Carmarthen 6 (4), Lancashire 5 (0), and 3 each in Kent (1), Sussex East (0), Sussex (4), Warwickshire (2), and Yorkshire East Riding (3). More than one case was reported from the following centres: London 6 (3)—in Battersea, Chelsea, Fulham, Greenwich, Kensington, and Stepney—Llandilo 4 (0), Tendring (Essex) 3 (0), and 2 each in Marple (0), Halstead (0), Lanbrook (0), Tamworth Urban (0), Tamworth Rural (0), Cuckfield (0), Llanelly (1), Swansea (0). In the two counties chiefly affected, Essex and Carmarthen, cases were notified in: Tendring 3, Halstead 2, and 1 each in Barking, Harwich, Ilford, and Dunmow; and in Carmarthen—Llandilo 4 and Llanelly 2. In the week under review, 1 (4) case was notified at Horsham.

The epidemic of acute poliomyelitis in Germany continues to decline: for the week ended September 24, 275 cases were recorded in the whole country, as against 386 in the previous week; the areas chiefly affected were: Cologne district 44 (88), Wiesbaden 23 (27), Düsseldorf 18 (19), Bavaria 55 (50), Württemberg 58 (55), Baden 17 (16), Saxony 33 (33), Austria 21 (18). On the other hand, an increase was noted in Holland for the week ended October 1, the notifications having risen to 44 (30). In the Province of South Holland there were 18 (8) cases, and 6 cases in the Province of North Holland. In Sweden during the first fortnight of September the numbers reported increased from 167 to 230, of which 85 were non-paralytic; the districts chiefly affected were: Jämtlands Rural 94, Jämtlands Urban 25, Kristianstads Province 23. During the same period there were 84 cases of acute poliomyelitis in Finland, of which 18 occurred at Helsinki.

Primary and Influenzal Pneumonia

Slight increases in the notifications of primary and influenzal pneumonia were observed in England and Wales and in London; an increased number of deaths were recorded for the same period—22 (16) and 2 (0) respectively. The counties with the greatest increases were: Derby 12 (8), Leicester 12 (8),

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

London 47 (33), Staffordshire 33 (24), Warwickshire 35 (21). At the time of going to press reports have been received of an increasing spread, especially of influenzal pneumonia, in Durham and Birmingham districts.

Diphtheria and Scarlet Fever

There was a drop in the notifications of diphtheria in England and Wales during the week—1,166, compared with 1,209 in the previous week—and in London—125, compared with 129. In Scotland an increase was recorded: Glasgow 71 (70), Aberdeen 9 (6), Fife County 15 (3), Perth 5 (0). Of the 28 deaths in the 126 Great Towns of England and Wales 3 occurred in Birmingham, and 2 each in London, Bradford, Liverpool, South Shields, Wallasey, Stoke-on-Trent, Newport. Four deaths from diphtheria were recorded in Glasgow and 1 each in Ayr and Paisley.

Notifications of scarlet fever in England and Wales fell during the week under review—1,734, compared with 1,776 in the previous week; but in London there was an increase—180 (155)—and in Scotland, where 389 (380) cases were notified. The areas chiefly affected were: Aberdeen 13 (11), Ayr 7 (2), Fife 30 (22), Dunfermline 9 (4), Glasgow 97 (82), Paisley 14 (11). There were no deaths from scarlet fever recorded in the British Isles during the week.

Measles and Whooping-cough

There was only one death from measles (at Rhondda) in the 126 Great Towns of England and Wales during the week. The first notifications of measles and whooping-cough since these diseases were made notifiable in the administrative county of London are available for publication in this week's issue. As stated in these columns on October 8, page 770, all cases of measles and whooping-cough occurring in a household at an interval of two months from any previous cases must be notified to the borough medical officer of health. Of the 24 cases of measles notified the chief were in Southwark 5, Stepney 4, and Battersea and Wandsworth 3 each. In Scotland the notifications rose from 13 to 17 in the week under review, the centres affected being Glasgow 13 (6), and 1 each in Dunfermline (0), Lanark County (2), Greenock (1), and Paisley (1). Of the 8 deaths from whooping-cough in the 126 Great Towns 2 occurred in Walthamstow and 1 each in Hendon, Twickenham, Luton, Portsmouth, Leeds, Salford. In London 43 cases were notified, distributed mainly as follows: 5 each in Islington, Bethnal Green, and Lambeth, 4 each in Bermondsey and Stepney, and 3 each in Hackney, Southwark, Wandsworth, and Lewisham. In Scotland there was a decided increase in the notifications of whooping-cough during the week—109 (94)—chiefly in: Glasgow 84 (79), Paisley 12 (2), Edinburgh 6 (2). Two deaths were recorded, both in Glasgow.

Cholera: Plague

During the week under review there were 280 (237) cases of cholera and 135 (122) deaths in the United Provinces of India and 1,670 (3,463) cases and 743 (1,526) deaths in the Central Provinces. During the four weeks ended October 8 the incidence of cholera declined in most of the provinces, with the exception of those of the lower Ganges valley (Bihar and Bengal), and Assam. In the Central Provinces the number of cases declined during the four weeks ended September 10 from 30,948 to 15,048; in the same period the number fell in the United Provinces from 1,410 to 999, and in Bombay Presidency from 2,062 to 1,147. In Assam 1,102 cases were notified in the four-week period September 4 to October 1, compared with 522 during the previous four-week period. During the week ended October 8, 95 (113) cases and 33 (38) deaths were recorded in Shanghai, and in Hong Kong 9 (7) cases and 6 (5) deaths. From the reports of the two anti-epidemic units of the League of Nations in China, it appears that the cholera situation in the provinces of Central China is well in hand and the spread of the disease westwards has been checked.

In India during the week under review there were 46 (166) cases of plague reported in the Central Provinces and 4 (7) deaths, 37 (37) cases and 31 (27) deaths in Burma, 23 (35) cases and 12 (15) deaths in Madras Presidency, and 12 (21) cases and 8 (20) deaths in Bombay Presidency.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 8, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.
† Death from puerperal sepsis.

‡ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

The Services

DEATHS IN THE SERVICES

Lieutenant-Colonel ERNEST EDWIN WATERS, Bengal Medical Service (ret.), died at Camberley on September 20, aged 66. He was born on July 21, 1872, and was educated at St. Bartholomew's Hospital and at Edinburgh University, where he graduated M.B., C.M. in 1893, proceeded M.D. in 1903, and subsequently took the M.R.C.P.Lond. in 1911. He gained the Maclean Prize in Military Medicine at Netley, and entered the Indian Medical Service as surgeon lieutenant on July 29, 1895, became lieutenant-colonel on January 29, 1915, and retired on July 19, 1927. He served in the Tirah campaign on the North-West Frontier of India in 1897-8, where he took part in the actions on the Malakand and also those of Dargai, the Sampagha and Arhanga passes, and the Bazar Valley, receiving the frontier medal with two clasps. Most of his service was spent in Bengal in civil employ, which he entered in May, 1899, serving as superintendent of the Presidency General Hospital, Calcutta, as deputy sanitary commissioner, and as resident physician of the Medical College Hospital. Later in his service he held several of the most important medical appointments in Bengal, the civil surgeoncies of Cuttack, Murshidabad, and Howrah successively, and the post of surgeon-superintendent of the Presidency European General Hospital, Calcutta. He was the author of a work on *Diabetes, its Causation and Treatment, with Special Reference to the Tropics* (1927). He had been for many years a member of the British Medical Association, was a representative at the Annual Meetings, 1934-8, and chairman of the Guildford Division, 1935-7.

Lieutenant-Colonel JOHN GREGORY JORDAN, Bengal Medical Service (ret.), died in London on October 5, aged 78. He was born on December 6, 1859, and was educated at Edinburgh University, where he graduated M.B., C.M. in 1883. He entered the Indian Medical Service as surgeon on September 30, 1886, became lieutenant-colonel after twenty years' service, and retired on April 18, 1918. He served on the North-West Frontier of India in the Mirazai campaign of 1891, receiving the frontier medal with a clasp. Most of his service was passed in Bengal in civil employ, which he entered in 1892. On the partition of Bengal in 1911, he was elected for service in Bihar and Orissa. During the war he reverted to military duty in April, 1916, and remained on military duty in India until his retirement.

Medical News

The William Blair-Bell Memorial Lecture will be given by Mr. T. N. A. Jeffcoate, M.D., F.R.C.S.Ed., M.C.O.G., on "Uterine Inertia," at the British College of Obstetricians and Gynaecologists, 58, Queen Anne Street, W., on Friday, October 28, at 2.30 p.m. All medical practitioners are invited to attend.

Dr. G. Jessel will deliver his presidential address on "Serial Skiagraphy in Pulmonary Disease" before the North-Western Tuberculosis Society at the Tuberculosis Offices, 352, Oxford Road, Manchester, on Thursday, October 27, at 3.15 p.m.

At the Royal Society of Arts on Wednesday, November 2, at 8.30 p.m., Lord Amulree will give an address on "Industrial Holidays." Tickets may be had from the secretary of the society, John Street, Adelphi, W.C.2.

Viscount Samuel will give the fourth Clarke Hall Lecture, "Is the Criminal to be Blamed—or Society?" in the Hall of Gray's Inn on Thursday, October 27, at 4.30 p.m., with the Home Secretary, Sir Samuel Hoare, in the chair.

The Kensington Division of the British Medical Association has arranged a meeting, to which all members of the medical profession are invited, at B.M.A. House, Tavistock Square, W.C., on Wednesday, November 16, at 9 p.m., when addresses on "The Place of the Doctor in Air Raid Precautions" will be given by Wing Commander E. J. Hodson, Inspector-General of Air Raid Precautions, and Dr. Norman Hammer, Medical Adviser to the Home Office Air Raid Department.

Professor Henry Cohen will deliver his presidential address on "The Medical Knowledge of William Shakespeare" before the London Jewish Hospital Medical Society at the Anglo-Palestinian Club, 43, Great Windmill Street, W., on Sunday, October 23, at 8.30 p.m.

A special meeting of the Institution of Heating and Ventilating Engineers will be held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., on Wednesday, November 2, at 7 p.m., when Mr. L. W. J. Henton will give an address on "Air-conditioning Requirements of Cinemas."

A meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday, October 28. At 5 p.m. there will be a business meeting, and at 6 p.m. Professor E. P. Cathcart will open a discussion on "The Feet of the Industrial Worker." Mr. C. Lambrinudi will show a film on "The Action of the Muscles of the Foot." Other speakers will include Mr. W. S. Creer, Dr. W. Blood, and Mr. Eric Gill. On Saturday, October 29, there will be a visit to Messrs. J. Lyons and Co., Ltd., Cadby Hall, W.

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, October 27, at 8.30 p.m., when a paper will be read by Sir Bernard Spilsbury on "The Medico-Legal Significance of Wounds."

A further wing of the Manor House Hospital, Golders Green, N.W., will be opened by Queen Mary on Monday, October 24, at 3 p.m. Invitations to the ceremony have been sent out by the president, chairman, and trustees of the Industrial Orthopaedic Society.

The 1938-9 programme of the West Kent Medico-Chirurgical Society is as follows: November 11, Dr. Macdonald Critchley, "Migraine." December 9, Purvis Oration by Sir Crisp English, "On Taking Stock." January 13, Clinical evening. February 10, Mr. Alistair L. Gunn, "Some Recent Advances in Midwifery." March 10, Mr. John G. Sandrey, "Genito-urinary Emergencies." April 14, Debate: "That Voluntary Euthanasia should be Legalized." Proposer, Dr. C. Killick Millard; seconder, Dr. Wm. A. MacIlraith; mover of negative, Dr. C. O. Hawthorne; seconder of negative, Mr. Stephen Power. May 12, President's address. Meetings are held at the Miller General Hospital, Greenwich, S.E., on Fridays at 8.45 p.m.

The North London Medical and Chirurgical Society has arranged the following programme for 1938-9: November 16, Medical clinical evening. December 14, Demonstration by Dr. Yeo and members of the staff of the x-ray department of the Royal Northern Hospital. January 18, Mr. W. B. Gabriel, "The Diagnosis and Treatment of Some Common Rectal Diseases." February 15, Surgical clinical evening. March 15, Mr. T. Anthony Green, "Treatment of Disease by Radiotherapy." April 19, Medical clinical evening. May 17, President's address and annual general meeting. All the meetings will be held at the Royal Northern Hospital, Holloway Road, N., on Wednesdays at 9 p.m.

The twenty-sixth French Congress of Medicine, which was to have been held at Marseilles on September 26, has been postponed until November 10 to 13. The following congresses which were to have been held this month have been indefinitely postponed: the twenty-fifth French Congress of Hygiene, the fourth annual Congress of French-speaking Electroradiologists, and the Franco-Yugoslav Medical Congress. The next congress of the Latin Medical Press, which was to have been held at Lisbon this year, has been postponed until the end of next summer.

L'Union Internationale contre le Cancer is arranging an "International Cancer Week" from November 23 to 30, which is to include an international conference to commemorate the discovery of radium, electrons, x-rays, and Hertzian waves; papers will be read by experts of various nationalities. The opening meeting will take place at the Sorbonne on November 23, when the President of the French Republic and other distinguished people will be present. Further information can be obtained from the secretary-general, 18, Rue Soufflot, Paris Ve.

The August issue of the *Bulletin de l'Office International d'Hygiène Publique* contains articles on small-pox, post-vaccinal encephalitis in the Punjab, typhus in Poland, scarlet fever, diphtheria, dysentery in Calcutta, Canada, Great Britain, Bulgaria, and the United States, and dengue in Cairo.

The publishing firm of Theodor Steinkopff of Dresden and Leipzig have founded a journal for research into old age, *Zeitschrift für Altersforschung*, the first volume of which appeared in July this year.

At the recent International Congress of Obstetrics and Gynaecology held in Amsterdam, where the principal subjects for discussion were eclampsia, thrombosis and embolism, and hormones, it was decided that the next congress should take place in Rome in 1942.

Yorkshire film exhibitors at a recent meeting in Leeds decided to proceed with their proposal to provide an "iron lung" for the General Infirmary at Leeds for use by all the hospitals in Yorkshire. They also agreed to form a committee to raise the necessary funds, probably by promoting a Sunday concert at one of the large cinemas in the city.

Up to April 1 of this year 983 pilots and other members of the staff of the Pan-American air traffic for the United States, Mexico, and Guatemala have been inoculated against yellow fever. The vaccine is supplied by the Rockefeller Foundation.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES ARE

EDITOR OF THE BRITISH MEDICAL JOURNAL, *Antology Westcent*, London.

SECRETARY, *Medisecra Westcent*, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Education in Switzerland

"AGRESTIS" will be grateful for information regarding schooling in Switzerland for two children, a boy of 12 and a girl of 13, whose father died three years ago of lung tuberculosis. Both react very strongly to the Mantoux test, and both have been treated on rest lines for symptoms which were considered to be due to the tuberculous infection. Both are now active and well, but the mother is anxious to take the children to Switzerland for two years. She proposes to live with them and to send them to school as day pupils. Schooling would have to be in one of the altitude zones, and ordinary schools (not schools for sickly children) are desired. They would probably have to go to separate schools.

Treatment of Psoriasis

"C. N." would be grateful for suggestions of any known remedy for psoriasis and for any new details of its pathology.

Origin of the Laryngoscope

R. S. S. writes: Your account (*Journal*, September 10, p. 604) of the origin of the laryngoscope, though accurate so far as it goes, does not go quite far enough. According to Morell Mackenzie (*Diseases of the Throat and Nose*, 1880, vol. i, p. 213) the first trace of the laryngoscope appears in 1743, when M. Levret, a distinguished French accoucheur, employed a speculum, which differed from the various *specula oris* then in use and consisted mainly of a plate of polished metal, for examining the throat. The laryngeal speculum of Bozzini (of Frankfurt-on-Main) is well known, and is illustrated in Morell Mackenzie's first volume (p. 213); it was first shown about 1804, and his publication on the subject appeared in 1807. Babington's (1829) and Liston's (1840) laryngoscopes were mentioned by you, but Avery's (1844), which resembled Bozzini's, was much more useful. It is true, however, that the use of the modern laryngoscope dates from Manuel Garcia (1855), Türk (summer, 1857), and Czermak (November, 1857). The first book in English on the use of the laryngoscope was written by James Yearsley, founder of the Metropolitan Ear, Nose, and Throat Hospital (*Introduction to the Art of Laryngoscopy*, London, 1862). Morell Mackenzie's book, *The Use of the Laryngoscope*, was published in London in 1865. Mackenzie, "the father of English laryngology," was assistant physician to the London Hospital, and became acquainted with laryngoscopy when he visited the clinic of Professor Czermak at Pesth in 1859. Türk of Vienna had read Garcia's paper, and tried unsuccessfully to employ the laryngeal mirror in the General Hospital of Vienna. Czermak borrowed the mirrors which Türk had laid aside, and, "being possessed of a most capacious pharynx, small tonsils and uvula, and a large laryngeal aperture," his investigations on his own larynx proved most successful. Türk afterwards claimed priority, but the general employment of the laryngoscope in medicine must be attributed to the enthusiastic teaching and brilliant demonstrations of Czermak.

Treatment of Pruritus Ani

Dr. SYLVIA ASHTON (London, E.18) writes in reply to "J. M." (October 1, p. 728): I have a patient who had pruritus ani, of no known cause, which cleared completely in two or three days after the application of calomel (hydrarg. subchlor.) used as a dusting powder and applied night and morning. Various cocaine ointments had had no effect.

Dr. CHARLES NYHAN (Co. Cork) also writes: "J. M." should first look carefully for any local lesion—fissure, haemorrhoids, worms, inflammatory conditions of the rectum or colon, effects of previous dysentery, etc.—each or any of which must receive its own specific treatment. A tablespoonful or more of sodium sulphate dissolved in a little over a wineglassful of boiling water should be taken warm first thing each morning. After evacuation an enema of strong saline solution (1 to 1½ pints) should be given. After this has been passed an iodoform suppository should be inserted deeply into the anal canal. Another enema should be given at bedtime, followed again by the insertion of a suppository. Relief of symptoms should be noted after two days, but the treatment should be continued for ten days and repeated if the symptoms return. I would be glad to hear from "J. M." the result of this treatment.

"R. A." also writes: I suffered from pruritus ani for nearly fifty years. I got into the habit of washing with soap and water after every evacuation. This gave considerable relief, but what gave me most relief during an attack—usually at night—was swabbing with surgical spirit. Three years ago I had my appendix removed, and since then I have had no recurrence of the pruritus. The only attack of appendicitis I had had previously was fifty-eight years before.

Income Tax

Proportion of Expenses

"XXX" is a partner in a large seaside town. He was unable to acquire his predecessor's residence, and in his present house has to give up both his sitting-rooms at surgery hours and other times. The inspector of taxes has written saying that he considers one-third of the whole expenses to be a reasonable proportion to set against the practice. "XXX" says he understands that two-thirds has generally been allowed.

* * * In our experience two-thirds is allowed only in exceptional circumstances; normally it does not leave enough to

cover private use. For example, one-third of £150 rent would usually be less than the private part of such a house would cost to rent. But in the circumstances mentioned a one-third allowance seems clearly inadequate, and we advise our correspondent to claim one-half, and carry his point to personal appeal to the local or Special Commissioners if necessary. Judging from the inspector's letter he seems to have overlooked two material points: first, that the ground floor is in terms of rent worth more than the others, and, second, that the garage is almost entirely "professional."

The Cash Basis

W. H." has hitherto been assessed on the cash basis, but "a new inspector" says this method is wrong, and is asking for information as to the amount of debts outstanding at April, 1937 and 1938, and for an estimate of bad debts so as to recalculate the profits on the earnings basis. Is this usual?

* * It has to be admitted that in strict law the "bookings" basis is correct; the cash basis is obviously more convenient, and for that reason is accepted by the Revenue authorities where the circumstances do not make it unfair. For example, it would not work equitably in the case of an increasing practice or in the early years of a new one, because the whole of the expenses are being charged but some of the earnings therefrom are not being credited. If the gross bookings of our correspondent's practice are steady we think the inspector should—and will on reconsideration—withdraw his request for the specified particulars, which he evidently proposes to use to adjust the "cash" figures to a "bookings" basis.

Motor Car Expenses

C. M. O." holds some appointments which necessitate a good deal of travelling. He has kept accurate records for some years and finds that they are "fairly uniform." He has therefore suggested to the inspector of taxes that he need not continue to keep the records for the future, but he declines to agree.

* * It is probably difficult for the inspector to agree, seeing that such records are officially desirable, and it may be that if "C. M. O." discontinued the records and next year made a definite statement that he was sure that his official mileage was not less than in the previous year, the inspector might then accept the statement. But unless the records are really troublesome we should advise our correspondent to go on with them.

Increase in Partnership Share

S. D." bought a one-third share in a partnership in January, 1935, and increased it to a half share in April, 1937. The firm's accounts are made up to December 31. He has paid both instalments of tax for 1937-8 on the one-third basis but is now told that he will have to make an additional payment to bring the tax up to one-half basis. Is that correct?

* * Yes. The "previous year basis" applies to the calculation of the firm's profits, so that if £x was the amount of the firm's earnings for the year to December 31, 1936, then £x is taken as the firm's income, for income tax assessment purposes, for the year to April, 1938. That assessment has to be divided between the partners in the ratio in which the profits are shared for the year of assessment, and therefore "S. D." will have to account for tax on half the assessment. ("S. D." refers to payment on the receipts of 1937, but there seems no reason why the 1936 basis of calculation of the firm's assessment should be set aside for the 1937 profits.)

Deduction for Assistant's House

M. H." has an assistant who lives at the branch surgery and pays 30s. a week rent. The house and surgery were originally semi-detached houses and were bought and adapted by "M. H." What should he deduct as an expense in this connexion?

* * He has two alternatives: (a) to exclude the 30s. rent from his professional receipts and to deduct only the expenses relating to the surgery, or (b) to include the rent and deduct the expenses incurred on the whole premises. The latter is frequently more convenient. The expenses deductible cannot be based on the capital cost of the premises or on what they previously produced in rent, but

on the facts as they exist now. They would include rates, repairs, and the amount of the net Schedule A assessment on the property.

LETTERS, NOTES, ETC.

Stolen Instruments

"M.D., F.C.O.G." writes: It is with some alarm that I hear of widespread thefts of surgical instruments from doctors' and consultants' cars, and quite recently I had a complete set of gynaecological instruments stolen from my car. If these stolen instruments had no market they would obviously be dumped somewhere by the thieves and in many cases would be recovered by the police, but in several cases I know of neither the thieves nor the instruments have been discovered. It seems not impossible that widespread dealing may be going on in stolen surgical instruments.

John Shaw Billings

Dr. MAZYCK P. RAVENEL writes from the University of Missouri: In your issue of August 27, 1938, p. 458, you give a review of the April number of the *Bulletin of the Johns Hopkins Hospital* which contains a series of papers, on John Shaw Billings. The statement that he volunteered for medical service with the Confederate Army is not correct. He was attached to the Army of the Potomac under General Hooker. Dr. Billings was a Northerner, and had no sympathy with Secession so far as the evidence goes, though he was very friendly to many Southerners after the war was over.

A Collection of Journals

Dr. CLAUD F. DRUITT (Springfield, The Avenue, Walton-by-Clevedon) has a complete collection of the *British Medical Journal* for the past thirty years, which he thinks might form the nucleus for a newly started medical library, and is willing to present them to anyone interested if packing and transit expenses were found. The volumes are carefully sewn together, with the indexes at the beginning of each, the whole being finished with a brown-paper cover and date label. Dr. Drutt has the volumes arranged on open shelving, which is built in sections and could easily be removed with the volumes. A photograph of the volumes on the shelving can be seen on application to the Librarian of the British Medical Association. Dr. Drutt also has a complete collection of the *Practitioner* since 1918. These are unbound, but arranged in order, and would be sent on the same terms to any medical library, or will be disposed of privately if desired.

Percaine Handbook

Percaine was first introduced by Ciba Limited (48, Southwark Street, S.E.1) in 1929; since that time some 2,000 papers have been published recording the results of clinical and pharmacological investigations of its properties. The *Percaine Handbook* is a review based on eighty-nine of these articles, to which detailed references are given. A brief account of the chemical, physical, and pharmacological characters of percaine is followed by a comprehensive survey of its clinical applications. Of particular interest is a detailed comparison of the techniques of spinal anaesthesia elaborated by Howard Jones, Etherington Wilson, Sebrechts, and other workers. The booklet will be sent on request to any medical practitioner.

Disclaimer

Mr. IVOR LEWIS writes: My attention has been drawn to sensational and inaccurate reports in the lay press of an operation recently performed at the North Middlesex Hospital. I need hardly say that these appeared without my consent or knowledge. The survival of a patient after a Trendelenburg operation for pulmonary embolism doubtless has the makings of a "good story," but one feels that the newshawks might at least allow it to be dealt with in the professional press in the first place!

Correction

In Fig. 5 illustrating Mr. Lake's article on "Infections of the Hand and Fingers" in the *Journal* of October 1, p. 717, there was a mistake in the legend. After (f) should have appeared "flexor longus pollicis" and not "extensor longus pollicis."

KEY TO CURRENT MEDICAL LITERATURE

GENERAL JOURNALS

Bulletin of the Johns Hopkins Hospital

*Influence of Tonsillectomy upon Course of Rheumatic Fever and Rheumatic Heart Disease. W. B. Allan and J. W. Baylor.—p. 111.

Tonsillectomy and Rheumatic Fever.—One hundred and eight patients subjected to tonsillectomy and adenoidectomy because of rheumatic fever, between 1910 and 1924, were re-investigated in 1935. Since rheumatic heart disease developed in only six of the forty-nine rheumatic patients not having cardiac involvement at the time of operation it is concluded that these operations are to be recommended in the treatment of rheumatic fever.

Significance of Cardiac Venous Congestion. J. McMichael.—p. 161.
Oestradiol Benzoate Therapy in Senile Vaginitis. T. N. MacGregor.—p. 113.
Notes on Four Cases of Post-partum Collapse. J. K. Sutherland.—p. 124.

Bromide Intoxication.—The possible dangers of bromide treatment are stressed and a description of the physical and mental effects of intoxication is given. The view is put forward that bromide intoxication can cause impairment of kidney function, many cases showing a raised blood urea, which falls when the intoxication disappears. The clinical picture is not protean, but is of an organic reaction type. Several cases are reported.

Can we "Breed Out" Cancer?—The answer is in the negative; not because of its mode of inheritance but because of the lateness of onset. To prevent from reproducing all who have cancerous ancestry is to discard most of the race. Knowledge of inheritance of cancer will not help us to breed it out, but may help us to treat earlier than we otherwise would some cases in which there is a family history of cancer.

Diphtheria Mortality in Large Cities of United States in 1937.—p. 524.
Determination and Sources of Vitamin D. E. Nelson.—p. 528.

Rabbit Anti-pneumococcus Serum.—Loughlin *et al.* describe in detail sixty-nine cases of pneumonia of various types treated with rabbit anti-pneumococcus serum. Three patients with injections of Type I and two of Type II succumbed, but in all five serum treatment was begun late in the disease and bacteraemia was present. In all other cases the blood stream was sterilized after the administration of the projected dose. A single dose cured forty patients. No severe untoward reactions were noted after the injection of unconcentrated refined rabbit serum, and the incidence of serum sickness was lower with rabbit serum than with horse serum.

Bile Peritonitis of Unusual Causation. K. L. James.—p. 311.

Gastric Surgery.—The scope of various operative treatments is discussed. The "physiological gastrectomy" (with preservation of the pyloric portion), advocated by Ogilvie in 1936, is now rejected, later jejunal ulceration having been found common. Medical treatment, faithfully followed, cures duodenal ulcer: operation is called for (1) in organic stenosis, and (2) in non-stenosing cases when there has been major haemorrhage (gastrectomy). In gastric ulcer, owing to the low acid level, the type of operation is less important, but gastrectomy is generally preferable.

- *Effects of "Water Diet" on Course of Typhoid Fever. L. Amhard, P. Barthelme, and P. Mandel.—p. 1209.
 *Stovarsol Therapy in General Paralysis. L. Marchand.—p. 1211.

"Water Diet" in Typhoid.—The authors show by means of charts from a number of cases of typhoid fever that a

diet consisting only of water (or at most weak tea or herbal infusions with a little saccharose, but no milk or any other fluid which may possibly serve as a nutritive medium for *B. typhosus*) will cure the subfebrile type of the disease, in which the temperature tends to remain more or less indefinitely a little above normal, in three or four days. Loss of blood, provided it be not excessive, has a similar, and perhaps also an immunizing, effect.

Stovarsol.—The author has treated 111 cases of general paralysis of the insane with stovarsol injections. Of these, seventy-one, or 64 per cent., made a "social recovery," ten (9 per cent.) were improved, fifteen (13.5 per cent.) were not improved, and fifteen died—nine of intercurrent diseases and six of general paralysis of the insane. By "social recovery" the author means that though the patients could not be regarded as organically cured they were sufficiently recovered to be able to resume their usual occupations and showed no mental symptoms.

 Diagnosis of Gonorrhoea and Atypical Gonococci. P. Asch.—p. 934.
 Short-wave or Diathermy Treatment in Peri-uterine Inflammatory Affections. T. Koller.—p. 937.

"Silvatic" Plague.—After a historical account of plague infection in California and the part played therein by ground squirrels, five Californian cases so infected are described. The importance of bacteriological investigation of blood, lymph-gland juice, or pus in suspicious cases is emphasized: as also that of care in dealing with ground squirrels, dead or alive. Twelve species of rodents are listed which have been found infected in the U.S.A. Rodents may show no anatomical lesions while their fleas are infective to guinea-pigs. North America must certainly be regarded as an infected zone; the dangers of a somewhat similar state of affairs arising in South Africa are discussed.

Bact. alcalescens in Infections of Urinary Tract and its Relation to Dysentery Bacilli (Eng.) E. Neter.—p. 597.

Exophthalmos in Graves's Disease.—Injection of acid extracts of the anterior lobe of the pituitary gland in guinea-pigs produces exophthalmos without dilatation of the pupils. This is probably due to the thyrotropic effect of these extracts. Clinical and experimental observations thus confirm that the exophthalmos is produced via the hypophysis as the result of stimulation of the centres in the diencephalon.

 *Advantages of Non-screen Roentgenography. H. H. Duerr.—p. 283.

Non-screen Radiography.—Radiography without intensifying screens has been made possible through the introduction of a new non-screen film, which is five to six times faster than the ordinary film. The advantages of the non-screen technique are: maximum detail, better definition, wider exposure latitude, and greater diagnostic value. The technique can also be used for most of the heavier parts of the body.

American Review of Tuberculosis

Baltimore vol. 38 August, 1938

 Pulmonary Gangrene complicating Pulmonary Tuberculosis. E. K. Geer.—p. 266.
 Mantoux Tests with Gottschall-Bunney Diluent for Tuberculin. E. Clarke.—p. 270.

Isolated Form of Pulmonary Tuberculosis.—The author constantly produced in rabbits lesions showing many of the characters of the isolated form of pulmonary tuberculosis in man by injecting a small blood clot containing tubercle bacilli through the jugular vein.

Annales d'Hygiène Publique, Industrielle et Sociale

Paris No. 9 September, 1938

- *Remarks on Decree of May 24, 1938, Relative to Unhealthy Premises. P. Jeannon.—p. 381.
 *Two Realizations within Scope of Departmental Office of Hygiene. G. Grenelleau.—p. 406.

Unhealthy Premises.—This article describes the purport and effect of recent amendments to "Article 12" dealing with unhealthy premises, whether buildings or not. The former and the revised texts are set out in parallel columns and appropriate comment is made upon the changes in legal powers and procedure thereby effected.

Two Realizations.—The author pleads for the establishment of two adjuncts (realizations) to the Health Department—namely, a "serum centre" and an "organization of donors"—on the grounds that such would effect better co-operation between curative and preventive medicine, and that better control would be exercised over the preparation of convalescent sera—for example, scarlet fever and measles convalescent sera—as well as over the donors from whose blood the sera are obtained.

Annals of Surgery

Philadelphia vol. 108 July, 1938

- Oral Ragweed Pollen Therapy: Clinical Results of Experiments on Gastro-intestinal Absorption. T. B. Bernstein and S. M. Feinberg.—p. 297.
- Infectious Diseases: Review of Current Literature. H. A. Reimann.—p. 305.

Bromsulphalein and Bilirubin Tests of Liver Function.—The rate of removal from the blood of injected bromsulphalein and of bilirubin was compared in normal and anaesthetized dogs after blockage of the reticulo-endothelial system, after ligation of the bile ducts, and after the injection of decholin. The two tests did not correspond, and it is tentatively suggested that diminished removal of bromsulphalein indicates impairment of the reticulo-endothelial system, while diminished removal of bilirubin indicates impairment of hepatic function.

Experimental Streptococcal Endocarditis.—Endocarditis was produced in dogs by traumatizing the cardiac valves and then administering a culture of *Str. viridans* either by injection or by mouth. Cure of the septicaemia and healing of the valves followed the administration of either sulphanilamide or merthiolate.

Boeck's Sarcoid.—A case of Boeck's sarcoid observed for two years is reported. Enlarged hilar glands first attracted attention. These disappeared after one year, but reappeared before death. At necropsy lesions were found in the lung, liver, spleen, myocardium, lymph glands, thyroid, and kidney. Marked oedema of the lymph glands was present, and it is suggested that the variation in size of the glands can be accounted for by the variation in their degree of oedema.

Archives of Neurology and Psychiatry

Chicago vol. 39 June, 1938

- Descending Connections from Hypothalamus. H. W. Magoun, S. W. Ranson, and A. Hetherington.—p. 1127.

- Primary Ventricular Haemorrhage. A. Gordon.—p. 1272.
- *Reduction of Increased Intracranial Pressure by Concentrated Solutions of Human Lymph Serum. J. Hughes, S. Mudd, and E. A. Strecker.—p. 1277.
- Symptomatic Psychosis in Case of Secondary Anaemia. J. Romano and J. W. Evans.—p. 1294.
- Meningeal Tumour in Foramen Magnum. W. J. Gardner, L. J. Carnosh, and J. C. Mc Nerney.—p. 1302.
- Direct Visualization of Dorsal Nerve Roots of Cauda Equina by Means of Myscope. J. L. Pool.—p. 1308.

Sweat Secretion.—Using the Minor sweating test the authors have observed and described normal sweating responses to heat and emotional and gustatory stimuli, and also after the subcutaneous injection of pilocarpine and mecholyl. Sweating depends on an intact nerve supply, and its observation

furnishes the most direct method of studying lesions of cutaneous sympathetic innervation.

Autonomic Innervation of Face.—Studying the Vulpian-Heidenhain-Sherrington phenomenon experimentally in cats, the authors conclude that it can be produced in the eyelid, lip, and tongue by stimulation of autonomic efferent fibres in the sensory divisions of the fifth nerve originating in the mesencephalic nucleus. These fibres normally initiate impulses for vasoconstriction, lacrimation, and salivation.

Reduction of Increased Intracranial Pressure.—Normal human blood serum concentrated four times by drying (lyophile serum) and redissolving in water has been used intravenously in doses of up to 200 c.cm. in cases of increased intracranial pressure and also in normal subjects. It was found more effective in reducing the cerebrospinal fluid pressure over a prolonged period than similar amounts of 50 per cent. sucrose. No untoward reactions were observed, but the possibility that these may occur was not excluded.

- Hypertrophic Interstitial Neuritis with Papilloedema. A. W. Diddle and R. L. Stephens.—p. 151.
- New Modifications of Benzidine Stain for Study of Vascular Pattern of Central Nervous System. M. M. Doherty, T. H. Suh, and L. Alexander.—p. 158.

Ascorbic Acid in Alcoholic Psychoses.—The authors have studied this substance in the plasma in 106 patients with alcoholic psychosis and fifty-eight patients who were used as controls. Their results indicate that patients with chronic alcoholism have a diminished ascorbic acid content in the plasma, which in some cases may reach a level as low as that in subclinical scurvy.

Thorotrast.—The effects of this drug have been very fully studied in animals, and it has been concluded that the clinical application of thorotrast for encephalography and ventriculography is dangerous because of its permanence, its radio-active destructive effect, and its ability to obstruct the flow of cerebrospinal fluid and lead to hydrocephalus.

Duodeno-gastric Intussusception: Its Clinical Application and Results J. K. Berman.—p. 139.
Origin of Carcinoma in Chronic Gastric Ulcer. S. H. Klein.—p. 155.

Stereomicroscopic Study.—A report of the technique and a description of the normal appearances of the bronchi and alveoli in animal and human lungs are given.

Tic Douloureux.—This is a comparison of the surgical and physiological results of partial section of the fifth sensory root performed by the subtemporal and cerebellar approaches.

Thrombosis of Left Internal Carotid Artery.—Two cases are described in which extracranial excision of a segment of the thrombosed vessel produced improvement in subjective findings and mental and motor reactions. It is suggested that the syndrome of signs of vascular disturbance in the middle cerebral distribution, together with unilateral reduction of pulsation in the common carotid artery and abnormal reactions of the carotid sinus on that side, is an adequate indication for exploration of the carotid system.

Beiträge zur Klinik der Tuberkulose

Berlin vol. 92 July 21, 1938 (Heft 1)

- Findings in Bronchographic Investigations. E. H. Meyer and O. H. Rolfs.—p. 1.
*Pulmonary Tuberculosis and Pregnancy. H. Straub and U. Schaare.—p. 31.

Significance of Culture of Laryngeal Swabs by Method of Schramm and Heredes in Detection of Open Pulmonary Tuberculosis. F. Böhm and A. Ekstein.—p. 77.
Disinfection of Linen Infected by Expectoration. E. Hailer.—p. 81.

Pulmonary Tuberculosis and Pregnancy.—This is a study of a small series of cases. In nine patients labour had a harmful influence on the disease. On the other hand, one patient with chronic military tuberculosis was not harmed by the pregnancy, and in three patients infiltrations actually disappeared after spontaneous labour. In other patients pregnancy did not influence the tuberculous lesion in any way. In most cases the fatal termination of an exacerbation was not prevented by spontaneous or induced abortion.

Thymophagen and Tuberculosis.—The author claims that his clinical trials show this drug to be a specific chemotherapeutic remedy for all forms of tuberculosis. Several references to papers by other Japanese on experimental findings are given.

Dyspnoeic Conditions and Insulin Shock.—Mild hypoglycaemic shocks favourably influence asthmatic attacks, and when repeated such shocks may cause a lasting improvement in the condition. Other dyspnoeic conditions, such as emphysema, are also favourably influenced by this therapy.

- Hippocampus and its Relations to Corpus Callosum. F. Tisley.—p. 1.
*Relative Refractory Period of Olfaction and Vision. H. Spotnitz and C. A. Elberg.—p. 78.

Relative Refractory Period.—The temporary lack of ability to perceive and recognize the nature of a weak stimulus following strong excitation is called the relative refractory state, is measured by its duration, and in all probability is primarily determined by the centrally situated neurones. The relative refractory periods of olfaction and of vision are often prolonged in the presence of supratentorial intracerebral growths, and there is some evidence suggesting that the duration of this state is a measure of the number and degree of deterioration of the central neurones involved.

*Observations on Cerebrospinal Fluid Pressure on Simultaneous Ventricular and Lumbar Puncture. G. E. Smyth and W. R. Henderson.—p. 226.
Critical Review: Twin Research in Psychiatry. E. T. O. Slater.—p. 239.

Electro-encephalogram in Cardiazol Convulsions.—The critical electrical changes accompanying cardiazol convulsions produced therapeutically in cases of schizophrenia are described. These appear two seconds after the injection as small waves at the rate of six per second over wide areas. After fifteen seconds there is an abrupt increase in the size and drop in the frequency of the waves in the superior frontal gyrus on one or both sides. This corresponds with the onset of the tonic stage of the fit. It spreads over the cortex, becomes more staccato in rhythm during the clonic stage, and ceases one to one and a half minutes after the injection. A similar electrical focus is found in idiopathic epilepsy, and its significance is not understood.

Pial Arteries.—The effects of changes in systemic blood pressure on the pial vessels were studied in cats. They contracted with a rise of pressure and dilated with a fall. The exact nature of the mechanism is not clear. It appears to be a vasomotor regulatory mechanism within the limits of the cerebral vascular tree, and it assists in keeping the blood flow to the brain constant during various conditions of the general circulation.

Cerebrospinal Fluid Pressure.—The relationship between the lumbar and ventricular cerebrospinal fluid pressure was studied in thirty-three cases of cerebral tumour. In five the pressures were normal; in twenty the pressure was raised equally in the lumbar sac and in the ventricles, and there was no block on jugular compression. In eight the ventricular pressure was higher than the lumbar. This difference was accentuated by withdrawal of lumbar fluid, and these cases were associated with a high early operative mortality, herniation of the temporal lobe, and brain stem haemorrhage.

Ultra-violet Radiation and Human Sweat.—Crew and Whittle have shown that the interposition of a film of human sweat partially screens the skin against erythema-producing radiation. They have computed that a sweat film of 1 mm. thickness transmits only about 27 per cent. of solar radiation effective in producing sunburn. The average thickness of

sweat on the forehead of a person profusely perspiring is about 0.07 mm., and under these circumstances roughly 30 per cent. of the surface of the skin will receive only about 75 per cent. of effective solar radiation.

 *Capillary Bronchitis Treated by Bleeding and Blood Transfusion. B. Tasso-vatz.—p. 288.

Capillary Bronchitis.—Infants with capillary bronchitis often arrive at the stage of asphyxia when the ordinary methods of treatment are of no avail. Recovery, however, may be brought about in some cases by withdrawal of blood from the infant followed by a blood transfusion. The longitudinal sinus is used, and 60 to 100 c.cm. of blood are withdrawn, followed by a transfusion of blood of an equal amount.

 Infectious Disease Returns: United States, Foreign, and Insular.—p. 1258.

Persistence of Typhus and Spotted Fever Virus.—Of the tissues tested—blood, spleen, brain, etc.—of the experimental animals (white rats, white mice, guinea-pigs) the brain was the most favoured site, and in the rats the viruses were found after a longer period and more consistently than in the mice or guinea-pigs. The periods were from 147 to 370 days after inoculation in different series, in guinea-pigs 60 to 120 days. It is suggested that this differential persistence may be used to distinguish endemic (murine) typhus from other rickettsial infections. Endemic typhus virus was maintained in native field mice for sixteen to thirty-six generations and persisted from 76 to 141 days. With Rocky Mountain spotted fever virus only one definitely positive result was obtained with the brain of a white rat thirty days after inoculation.

 Deaths during Week Ended July 9, 1938: Deaths in Group of Large Cities in United States; Death Claims Reported by Insurance Companies.—p. 1311.
 Infectious Disease Returns: United States, Foreign, and Insular.—p. 1312.

Disabilities among Employees.—This is an analysis of the disabilities causing absence from work among the employees of the Boston Edison Company during the five-year period 1933 to 1937 inclusive. The average number of days absent annually for males was 8.4 and for females 6.0. Frequency of disability showed no decline from year to year, but the period of absence showed a downward trend. The incidence of illness and the nature of the illnesses among different groups of employees are compared in tables and graphs.

Antagonism of Malaria Parasites.—This is a preliminary report on the effects of combining *P. vivax* and *P. malariae* for the treatment of paretics. When administered concomitantly one species, not always the same, rapidly became predominant, while the other tended to disappear. There is an apparent antagonism between the two species.

 Unsuccessful Treatment of Malaria with Sulphonamide Compounds. G. H. Faget, M. R. Palmer, and R. O. Sherwood.—p. 1364.
 Deaths during Week Ended July 16, 1938: Deaths in Group of Large Cities in United States; Death Claims Reported by Insurance Companies.—p. 1367.
 Infectious Disease Returns: United States, Foreign, and Insular.—p. 1368.

Dental Caries.—A preliminary survey indicates that there exists a familial resemblance in caries immunity and caries susceptibility. Two or more immunes were found in thirty families, and two or more susceptibles in sixteen families, but only in two families were both an immune and a susceptible found.

State and Insular Health Authorities, 1937.—Directory with Date as to Appropriations and Publications.—p. 1468
Deaths during Week Ended July 23, 1938: Deaths in Group of Large Cities in United States; Death Claims Reported by Insurance Companies.—p. 1479
Infectious Disease Returns: United States, Foreign, and Insular.—p. 1480

Precipitation, etc., of Antimeningococcus Sera.—In a study of a number of antimeningococcus sera it was found that in the majority a definite correlation existed between the type-specific precipitins as estimated by the "plate" method and the mouse-protective activity. In all instances if no precipitins were demonstrable no mice were protected; if precipitins were demonstrable the serum was capable of protecting mice.

Revue de Chirurgie

Paris vol. 57 June, 1938

Study of Certain Metabolic Changes Produced by Surgical Operation M. A. Delzer.—p. 350.
Operability and Extent of Operation in Cancer of Rectum in Female. M. M. Ducuing and G. Rimoud.—p. 423.
*Treatment of Abscess of Cerebellum. M. L. Léorat.—p. 444.
Three Cases of Fracture of Vertebral Column Treated by Infiltration with Novocain. M. M. Junc and Christias.—p. 458.

Cerebellar Abscess.—The treatment recommended in this article is primarily surgical, but is supplemented by medical and vaccine therapy. The technique of the operation is fully described; it is carried out in two stages. Owing to the gravity of the condition the proportion of cures is only 25 per cent.

*Hemibolism and Nucleus of Luys. M. H. Marcus and H. Sjögren.—p. 1.
Nervus of Lateral Femoral Cutaneous Nerve of Thigh in Course of Aneurysm of Abdominal Aorta. A. de Castro.—p. 29.
*Role of Hypertonic Solutions in Treatment of Migraine. G. Villey, J. F. Buvat, and Mme Buvat-Pechon.—p. 32.

Hemiballism.—The authors describe in detail first the anatomical relations of the nucleus of Luys, and then five cases in which a lesion of the nucleus had given rise to hemiballism. They conclude that a lesion of the nucleus is necessary for this symptom, as adjacent lesions may produce athetosis but not hemiballism.

Migraine.—Hypertonic serum has been found to cause the disappearance of migraine headache in approximately fifteen minutes. The pharmacological and therapeutic aspects of these findings are discussed.

Rivista di Neurologia

Naples vol. 11 April, 1938

On Presence of Neurofibrillary Net of Donaggio in Vesicular Cells of Mesencephalon. P. Jedlowski.—p. 160
Problem of Hallucination at Eleventh International Congress of Psychology. M. Gorziano.—p. 166.

Donaggio's Reaction in Epilepsy.—Donaggio's precipitation reaction due to the abnormal amounts of colloids in the urine and cerebrospinal fluid has been investigated in epilepsy. The reaction is positive, or if previously positive increased, immediately after the fit. The maximum reading is generally found from twelve to twenty-four hours afterwards, though sometimes it occurs in six hours and sometimes as late as forty-two hours. The intensity of the reaction on Donaggio's scale is on the average 33, sometimes being as high as from 45 to 51. In eighty-eight cases the duration of the reaction was on the average 106 hours, with a minimum of 42 and a maximum of 192. If the test is done at frequent intervals each patient shows a similar curve of intensity and duration for his fits which differs from the curves of other patients. Cardiazol convulsions produce a positive reaction, but it is much less intense and lasts a much shorter time than that seen in a true epileptic fit. Unless the

fits are very prolonged hysterical convulsions produce no reaction, and, even if present, in such prolonged attacks the reaction is feeble and of short duration.

*Problem of Traumatic Parkinsonism. F. Vizioli.—p. 185
Medullary Tuberculosis Masked by Necrotic Myelitis. G. Gluck and B. Garau.—p. 219.
Spasmodic Scoliosis in Differential Diagnosis of Lumbosacral Pain Symptomatic of Compression of Caud. Equina and Protracted Idiopathic Lumbosacral (Sciatic) Pain. C. Masci.—p. 247

Traumatic Parkinsonism.—The author describes three cases of uncomplicated Parkinsonism following cranial injury. All three cases had suffered from epidemic encephalitis and the trauma had precipitated the Parkinsonian syndrome, but in the author's opinion was not the primary cause. It is argued that the morbid anatomy of the syndrome, and in fact all considerations in relation to it, make it exceedingly unlikely that any cranial trauma, and especially a cranial injury, could be truly causal.

Results of Progressive Paralysis treated with Malena in Psychiatric Institute of Florence. G. Taddei.—p. 503.
Progressive Paralysis occurring in Four Subjects who contracted Syphilis contemporaneously from Same Source. G. Taddei.—p. 524

Basal Metabolism.—The basal metabolism was investigated in fifty cases of cerebral tumour confirmed on the operating table or at necropsy. The tumours were divided into three groups: (1) those affecting the anterior cranial fossa, which showed a normal basal metabolic rate even when intracranial hypertension was present; (2) those occupying the middle cranial fossa, including tumours of the hypophysis and the region of the sella, which showed marked lowering of the rate, thus confirming the opinion of the author that the region of the third ventricle is specially concerned with the regulation of the distribution of energy; and (3) those occupying the posterior fossa, in many of which cases the rate was definitely lowered.

Peripheral Pains.—The author reports four cases of sciatic neuralgia, of which three were cured by intradermal injections of novocain and one by percutaneous injections, in all of which there was a rapid remission of symptoms. In two cases of facio-cervical neuralgia the author obtained a complete and lasting relief of pain by intradermal novocain, and in a patient with frontal sinusitis a percutaneous anaesthesia, tried as an experiment, produced a rapid and complete relief of pain in a few minutes. The author considers that the mechanism of this treatment consists of the establishment of a synaptic block which interrupts the waves of stimuli conveying the pain sensation.

TUBERCULIN P.P.D.

*An improved
Diagnostic Tuberculin*

A PURIFIED protein derivative prepared from standard Tuberculin by the method described in the *American Review of Tuberculosis*, 25 : 724, 1932, has been introduced under the name Tuberculin P.P.D.

Hitherto, the interpretation of the intradermal reaction for the diagnosis of tuberculosis, and particularly comparison of the results of different clinicians, has been hampered by the presence of impurities in the various tuberculins used. For several years past the Research Department of Parke, Davis & Company has been in co-operation with the Research Committee of the National Association of Tuberculosis in America, in an endeavour to develop a standard tuberculin. The purified protein derivative, which is an outcome of these investigations, offers the advantage of greater accuracy, greater sensitivity and greater convenience.

In the preparation of the purified protein derivative, extraneous proteins are eliminated. The purified material is supplied in tablets, each containing a definite weight (0.0002 mgm., or 0.05 mgm.). The tablet dissolves promptly in the sterile buffered diluent supplied in each package. Fresh solutions should always be used, but the dry tablets may be kept for a period of five years without deterioration.

Further details of Tuberculin P.P.D. will be supplied on request.

A Solution to a **HEALTH PROBLEM**

"Sunshine and blue skies; farms and homesteads nestling among mountains and hills; blossoms of peach and plum filling the valley with colour; the perfume of orange groves; the profusion of wild flowers; the camp fire and the thrill of wild game in the Low Veld; the picturesque kraals and laughter-loving natives; the quest of open roads trailing to far horizons; the sparkling air of the High Veld; sea and sun bathing on golden beaches; the bright warm days and cool starlit nights—these memories and the joyous feeling of health and fitness after my last holiday in South Africa will lure me back there before long."

These are a recent visitor's impressions of a South African holiday.

Those concerned with problems of health might well consider the benefits to be derived from exchanging the rigours of a European Winter for "Sunshine and blue skies." It is now only a fortnight's voyage to

SOUTH AFRICA

Illustrated brochures, including one entitled "Medicinal Springs of South Africa," are obtainable from the Travel Bureau, South Africa House, London, W.C.2.

ERGOAPIOL (SMITH)

AMENORRHEA - DYSMENORRHEA MENORRHAGIA - MENOPAUSE

Today, as for years, Ergoapiol (Smith) is the accepted medicament in combating those menstrual anomalies which may be traced to constitutional disturbances; atonicity of the reproductive organs; inflammatory conditions of the uterus or its appendages; mental emotion or exposure to the elements.

The physician readily can ascertain whether his prescription for Ergoapiol (Smith) has been correctly filled by dividing the capsule at the seam, thus revealing the initials M.H.S. embossed on the inner surface, as shown in photographic enlargement.

How Do You Get Such Fine Radiographs?

THIS frequent inquiry, users of the new Victor model F-3 Portable-Mobile X-ray Unit tell us, is another source of continued satisfaction. Owners are producing uniformly good diagnostic radiographs because this practically designed unit is simple and easy to operate—accurately. The F-3 has surprising power for so small an X-ray unit. Yet this power combined with its compactness and portability, make it a valuable diagnostic aid which can be used wherever there is electricity. The principle of complete oil-immersion of all high voltage parts accounts for this unusual compactness and high efficiency. Moreover, it makes the F-3 absolutely shockproof. Low in cost, the F-3 is readily within your reach. Your request for Pub AX4 will bring complete particulars without obligation to you.

INDICATIONS FOR 'SANATOGEN'.

No. 18

THE PROTEIN MINIMUM

The value of 'Sanatogen'

Considerable doubt exists as to the accuracy of the alleged diet of the "perfect boy" recently adduced by Sir Leonard Hill as demonstrating that a vegetarian can healthily subsist on a much lower protein and calorie-yielding intake than is necessary for a mixed feeder. The fact that the nitrogen excreted in the form of urea alone exceeded that contained in the proteins said to have been consumed would seem to be conclusive of erroneous information as to intake. Even leaving out of account the nitrogen retention essential to growth, it is known that about 8 per cent. of the nitrogen normally eliminated is in the form of amino-acids and ammonia, whilst about 20 per cent. is included in the so-called "residual nitrogenous substances". Of these there is no mention; nor is allowance made for them.

It therefore remains probable that we cannot safely prescribe less than Hutchison's minimum of 80 grammes of protein daily for adults; and of this one third should belong to the A.I group—that is, the group containing the greater number of essential amino-acids—especially tryptophane, tyrosine, and phenyl-alanine.

Whilst grossly excessive protein intake is undesirable, it is established "that the resisting powers of those whose food contains a low protein allowance are always weak; and those nations in whose diet there is a very small amount of protein easily succumb to disease and fall a ready prey to epidemics". There seems to be little doubt that certain amino-acids exercise an inhibitory action on the growth of bacteria. And McDowall points out that "those recovering from illness, or building up new tissue, require additional proteins, as evidenced by the fact that their nitrogen excretion is reduced".

Whilst it would be unwise to rely even for our protein requirements on any single article of food, there are few diets that would not be materially increased in hygienic value by the addition of a generous supply of milk. Hence the great value of milk casein preparations, such as 'SANATOGEN', as a supplement to a vegetarian regime, and to the dietaries of invalids and growing children. In all these instances there is a considerable risk of nitrogenous disequilibrium.

'SANATOGEN'

(Trade Mark)

A brand of Casein and Sodium Glycerophosphate

Sold by all chemists price 2/3 to 19/9

DOSAGE. For children and adults two teaspoonsful three times daily, or according to circumstances. For infants $\frac{1}{2}$ teaspoonful added to each bottle feed.

The word 'SANATOGEN' is the Trade Mark of Genatosan Ltd., and denotes their famous brand of Casein and Sodium Glycerophosphate. A 'GENATOSAN' product made by GENATOSAN Ltd., Loughborough, Leicestershire.

Clinical samples and literature available on request to

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE

A thorough investigation

(reported in "The Analyst," 1936, Lxi, 310.)

could find no tea on the market which was free from tannin

The following facts about tea and tea tannin have been established by recent clinical and laboratory experiment:—

- [A] Tea as normally drunk is harmless and has no ill effects whatever on the human body. The amount of caffeine and tea tannin in tea is pharmacologically small.
- [B] Tea tannin is a different substance from the tannic acid of the Pharmacopœia, which is a Pyrogallie tannin, and the two should not be confused.
- [C] Clinical experiments have shown that the action of tea tannin is very much milder than that of tannic acid, and the different composition of the two tannins is proved by the fact that the tannic acid of the Pharmacopœia is about 25 times stronger as an acid than tea tannin.
- [D] Many common beverages besides tea contain similar tannins and in comparable amounts.
- [E] If there were any teas completely free from tannin, they would be almost entirely tasteless.

How We Assist in the Purchase of Medical Practices

Scotland's Oldest Insurance Company is prepared to assist Doctors in the buying of Medical Practices or Partnerships. The purchase price is repayable over a term of years, and a Life Assurance Policy is taken out as a collateral security. This scheme makes it unnecessary for a Doctor to approach his friends to act as guarantors, and enables him to pay for his practice out of income. After the repayment of the loan, the Life Policy becomes a valuable asset to the Doctor.

Many Doctors have already established themselves in practice with the aid of the "Caledonian" Scheme. The Interest Rates are particularly moderate. *The Accountant's charges for investigating the practice and the Legal Fees for preparation of the deeds and documents in connection with the Loan are paid by the Company in completed cases. Arrangements can be made to meet special cases.*

Full particulars on application to the Head Office, or to any of the Company's Branch Offices.

For 25 years, Medical Authority throughout the world has recognized the Curtis Abdominal Support No. 1 as the most efficient support for all forms of Abdominal Ptois. The even anterior-posterior pressure without undue constriction

of the abdomen has been found by far the most satisfactory; and with this Curtis has combined a lightness in weight and a freedom for bodily movement which is gratefully acknowledged by thousands of wearers.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

The Iron Jelloid Company, Ltd., King George's Avenue, Watford, Herts.

And Finally...

When satisfactory convalescence from pulmonary disorders depends on a healthy, invigorating atmosphere, Bournemouth offers the ideal winter residence. Long hours of sunshine, sheltered situation, and the resinous perfume of the thousands of pine trees combine to expedite the successful recovery of normal health and strength.

Pine, Vapour,
and Swimming
Baths, all of SEA
WATER, are
available at the
Pier Approach
Baths during the
Winter.

CRICHTON ROYAL, DUMFRIES

FOR

NERVOUS AND MENTAL DISORDERS.

This Hospital has every facility for complete investigation of the above conditions, and provides all forms of modern treatment including psychotherapy, physiotherapy, and recreational therapy. Cases of alcoholism and drug addiction are admitted. The Hospital has separate units fully equipped for X-ray work, radiotherapy, short-wave therapy, and hydrotherapy (swimming bath, prolonged baths Scotch and Vichy douches Plombières treatment, electric and Turkish bath cabinets, etc.) There is a fully equipped gymnasium under qualified instructors. Facilities are provided under special recreational therapists for all indoor and outdoor games, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens.

The Hospital has its own Cinema, Library and Hairdressing Saloon. Terms include regular motor drives. Private rooms, suites or villas are available and special nurses can be provided.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country and include an extensive farm (F.T. herd), gardens and orchards.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week. Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Superintendent, P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law.

Lecturer Dr J O OLIVER, M.B., B.S., M.R.C.S
For further particulars apply to the Dean.

IMPERIAL BUREAU OF ANIMAL NUTRI- TION, ROWETT RESEARCH INSTITUTE, ABERDEEN

Applications are invited for the post of DEPUTY
DIRECTOR of the Imperial Bureau of Animal
Nutrition, which is centred at the Rowett Research
Institute, Bucksburn, Aberdeen, Scotland.

The work of the Bureau consists mainly in the
collection and collation of scientific information on
nutrition (human and animal) and its dissemination
to research workers in countries of the British
Commonwealth and abroad.

Applicants should possess an honours degree in
Science or a degree in Human or Veterinary
Medicine. They should have experience in research
on nutrition. A knowledge of foreign languages
is desirable and overseas experience will be an
advantage.

The salary scale is £400-£700-£800-£25-£900.

The initial salary within the scale will depend on
the qualifications and experience of the person
appointed. For a properly qualified applicant early
promotion to the £600 level is probable.

The person appointed will be included in the
Federated Superannuation Scheme for Universities
after one year's probation.

Applicants should state age, experience, and
qualifications and give at least two testimonials
or references.

Applications should be addressed on or before
November 19th to—

SIR DAVID CHADWICK,

The Secretary,
Imperial Agricultural Bureau,
2, Queen Anne's Gate Buildings,
London, S.W.1.

COUNTY BOROUGH OF DEWSBURY.

DEPUTY MEDICAL OFFICER OF HEALTH
and
DEPUTY SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified
and registered medical practitioners for the post
of Deputy Medical Officer of Health and Deputy
School Medical Officer.

Applicants should have had at least three years'
experience since qualification and possess the
D.P.H. The duties include general Public Health,
School Medical work (including refractions), Child
Welfare, and Tuberculosis.

The salary is £600 per annum, rising by annual
increments of £25 to a maximum of £700, and a
motor-car allowance of £50 per annum. The
appointment will be subject to the provisions of the
Local Government and Other Officers' Super-
annuation Act, 1922, and the successful candidate
will be required to pass a medical examination.

Particulars of the duties and terms and conditions
of the appointment, together with application form,
may be obtained from Dr. J. F. Galloway, Medical
Officer of Health, Public Health Department,
Municipal Buildings, Halifax Road, Dewsbury, to
whom applications, accompanied by copies of not
more than three recent testimonials, should be
delivered not later than Monday, October 31st.

Canvassing in any form will be a disqualification.
Town Hall, HOLLAND BOOTH,
Dewsbury. Town Clerk.
October 10th, 1938.

CITY OF COVENTRY.

ASSISTANT MEDICAL OFFICER (Woman).

Applications are invited from duly qualified and
registered women Medical Practitioners under 40
years of age for the post of Assistant Medical
Officer in the City of Coventry Public Health
Department. The duties will be in connexion with
the maternity and child welfare scheme. Candidates
should possess a Diploma in Public Health, and
preference will be given to those having special
experience in the conduct of ante-natal clinics.

The salary will be £500 per annum, rising by
annual increments of £25 to a maximum of £700.
The officer appointed will be required to devote her
whole time to the duties of the post.

The appointment will be subject to the pro-
visions of the Local Government and Other Officers'
Superannuation Act, 1922, and the successful candi-
date will be required to pass the necessary medical
examination as to fitness and to contribute to the
Superannuation Fund.

Applications, together with copies of three recent
testimonials, must be made on the prescribed form
(which may be obtained on request) and must reach
the undersigned on or before November 3rd, 1938.

The Council House, A. MASSEY, M.D.,
Coventry. Medical Officer of Health.
October 17th, 1938.

DERBY CITY HOSPITAL.

ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Assistant
Resident Medical Officer (male) at the above Hos-
pital of 300 beds. This Hospital provides treatment
for acute medical and surgical cases, obstetrics, and
children's diseases, etc.

Candidates must be registered in medicine and
surgery.

The appointment is for a period of six months;
two months' notice of termination of duties may be
given on either side. The successful applicant will
be required to commence duties as soon as possible.

Salary at the rate of £200 per annum, with board
and residence.

Applications, stating age, experience, and accom-
panied by three recent testimonials, should be sent
to the undersigned as soon as possible.

October 10th, 1938.

COUNTY OF LINCOLN—PARTS OF LINDSEY.

PUBLIC HEALTH DEPARTMENT.

SENIOR ASSISTANT AND DEPUTY COUNTY
AND SCHOOL MEDICAL OFFICER.

The Council invite applications for the above
appointment at a salary of £720 per annum, which
sum includes emoluments valued at £100, with an
allowance for travelling according to the Council's
scale.

Applicants should be under 40 years of age and
hold a special qualification in State Medicine or the
Diploma in Public Health.

Experience in Public Health administration, with
a sound knowledge of the modern methods of the
diagnosis and treatment of tuberculosis, is essential.

Terms and conditions of appointment, together
with application forms, can be obtained from the
undersigned. Applications, which must be accom-
panied by copies of three recent testimonials, should
be received not later than Saturday, November 5th,
1938.

W. S. H. CAMPBELL,

qualified in accordance with the Regulations of the
Minister of Health. The possession of the D.P.H.
will be an advantage.

Salary £500 per annum, rising by annual incre-
ments of £25 to £700.

The appointment is subject to the provisions of
the Local Government and Other Officers' Super-
annuation Act, 1922.

Further particulars and forms of application may
be had from the undersigned, to whom all appli-
cations, together with copies of not more than three
recent testimonials, should be addressed not later
than Saturday, November 5th, 1938.

J. CHARLES McGRATH,
County Hall, Clerk of the County Council
Wakefield
October, 1938.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

*Fuller information can be obtained from The Director
of Medical Services, Air Ministry, Kingsway, London.*

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred; and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

COUNTY BOROUGH OF PRESTON. ASSISTANT SCHOOL MEDICAL OFFICER.

The Council invite applications from registered Medical Practitioners (male) for the position of Assistant School Medical Officer, at a salary of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

The duties are mainly in connexion with the School Medical Service, but a certain amount of time is given to the Blind Persons Act, 1920, Diphtheria Immunisation, and Infectious Diseases.

Candidates must have had not less than three years' postgraduate experience, including resident hospital appointments, and must have had special experience in refraction work. Special experience in the diseases of children will be an advantage.

The person appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Application forms, together with further particulars, can be obtained from the undersigned, to whom they must be returned and endorsed "School Medical Officer" on or before noon on Monday, November 7th, 1938.

HERBERT E. NUTTER,

Municipal Building, Town Clerk.
Preston.
October 12th, 1938.

HEBBURN URBAN DISTRICT COUNCIL. MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Urban District Council invite applications from fully qualified Medical Practitioners for the whole-time appointment as Medical Officer of Health and School Medical Officer, at a total inclusive annual salary of £800. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The successful applicant will be required to devote the whole of his time to the duties of the appointment and will not be allowed to engage in private practice. Further particulars, together with a form of application, may be obtained from the undersigned.

Applications, accompanied by copies of not more than three recent testimonials, endorsed "Medical Officer of Health" must reach the undersigned not later than November 2nd, 1938.

Canvassing the members of the Council in any form will be a disqualification.

Council Offices, ERNEST FOXALL,
Hebburn, Co. Durham. Clerk of the Council.
October 12th, 1938.

HULL CORPORATION HEALTH DEPARTMENT. ASSISTANT MEDICAL OFFICER OF HEALTH (for Port Health Work).

Applications are invited from duly qualified medical men, under the age of 40 years and of not less than three years' standing in their profession, for the appointment of Assistant Medical Officer of Health.

Salary £600 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700.

Candidates must hold a registered degree or diploma in State Medicine or Public Health. Experience in Port Health Work and Infectious Diseases will be considered special qualifications.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Thursday, November 3rd, 1938.

NICOLAS GEBBIE, M.D.,

Medical Officer of Health.

Health Department,
Gulldhall, Hull.
October, 1938.

HULL CORPORATION HEALTH DEPARTMENT. CONSULTANT OBSTETRICIAN AND GYNAECOLOGIST.

Applications are invited from registered Medical Practitioners for the appointment of Consultant Obstetrician and Gynaecologist (part-time) to the Corporation's Hospitals, Institutions, Clinics, etc.

Candidates must be Fellows of one of the Royal Colleges of Surgeons and Members or Fellows of the British College of Obstetricians.

Applications, on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Monday November 7th, 1938.

NICOLAS GEBBIE, M.D.

Medical Officer of Health.

Health Department,
Gulldhall, Hull.
October, 1938.

ESSEX COUNTY COUNCIL. JUNIOR ASSISTANT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the appointment of Junior Assistant Medical Officer at the Black Notley Sanatorium, near Braintree.

This sanatorium contains 300 beds for the treatment of pulmonary and non-pulmonary tuberculosis in men, women, and children, and possesses all modern facilities for diagnosis and treatment, and a staff of visiting specialists.

The appointment is limited to a period of one year, and the salary will be at the rate of £250 per annum, together with board, lodging, and laundry. The successful applicant will be required to pass a medical examination, and will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application.

Preference will be given to candidates who have held an appointment as House Surgeon with orthopaedic experience.

Applications, in candidate's own handwriting, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials (which will not be returned), should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Thursday, October 27th, 1938.

County Hall, E. S. HOLCROFT,
Chelmsford. Clerk of the County Council.
October 10th, 1938.

SWANSEA COUNTY BOROUGH. ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite the applications of women Medical Practitioners for the post of Assistant Medical Officer to assist with the medical services of the Corporation.

Special experience in the treatment of venereal diseases of women and children is essential; Resident Hospital, Mental Deficiency, School Medical Service, and Maternity and Child Welfare experience are desirable additional qualifications.

Salary £500, rising by annual increments of £25 to £700. The appointment is subject to the approval of the Ministry of Health and Board of Education.

Applications, on special forms which can be obtained from Dr. Thomas Evans, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than Thursday, November 3rd, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned position. Experience in a resident appointment in a general hospital for at least six months desirable. Married quarters not available.

QUEEN MARY'S HOSPITAL FOR CHILDREN, Carshalton, Surrey (1,284 beds). There are special departments for rheumatic and orthopaedic conditions, for congenital malformations, and for nutritional diseases.

ASSISTANT MEDICAL OFFICER (Grade II). Salary £250 a year, together with board, lodging, and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division 2A, County Hall, S.E.1, returnable by October 31st.

Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Grade I) — Salary £350-£25-£425, with board, lodging, and washing.

(a) PADDINGTON HOSPITAL, Harrow Road, W.5.

(b) HACKNEY HOSPITAL, Homerton High Street E.9.

Obstetrical and gynaecological experience essential (both positions).

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2A), County Hall, S.E.1, returnable by October 28th. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners with appropriate qualifications for two appointments as ASSISTANT PATHOLOGIST at Group Laboratories in the Council's pathological service. Salary £650-£25-£800.

Candidates should have special experience in one or more branches of pathology in relation to the diagnosis and treatment of disease.

Forms of application and further particulars (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, Westminster Bridge, S.E.1, returnable by October 31st.

Canvassing disqualifies.

STAFFORDSHIRE COUNTY COUNCIL. ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from medical men holding the Diploma of Public Health for the above post. Candidates should have had at least three years' experience in the practice of their profession subsequent to qualification. Preference will be given to those who have held residential hospital appointments.

The person appointed will work under the direction of the County Medical Officer and the duties of the office will include school medical and maternity and child welfare work, in addition to such general public health work as may from time to time be prescribed.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700 per annum, subject to a deduction of 5 per cent. established under the Local Government and Other Officers' Superannuation Act, 1922.

The successful candidate will be required to undergo a medical examination and to produce a birth certificate.

The appointment will be subject to three calendar months' notice on either side.

Forms of application may be obtained from the undersigned and should be returned by "first" post on October 27th, 1938, together with copies of not more than three testimonials.

Candidates must state in their applications whether or not they are in any way related to a member of the County Council.

Canvassing, either directly or indirectly will be a disqualification.

Candidates receiving no reply by November 12th, 1938, may assume the vacancy to be filled.

H. L. UNDERWOOD,
Clerk of the County Council.

County Buildings,

Stafford.

October 10th, 1938.

DEVON COUNTY COUNCIL. PSYCHIATRIST TO THE COUNTY MENTAL DEFICIENCY AND EDUCATION COMMITTEES.

Applications are invited from duly qualified Medical Practitioners (male or female) for the above appointment.

The officer will be on the staff of the County Medical Officer and will work under his supervision and control.

The officer will be responsible for the work of ascertainment and certification of the Mentally Defective, and will have certain supervisory duties in respect of the three Certified Institutions for the Mentally Defective controlled by the Council.

The officer will also be required to advise in cases of educational retardation and behaviour disorder in School Children.

Salary, in accordance with the Askwith Scale will commence at £750 per annum, and rise by three biennial increments of £50 and one of £37 10s., amounting to £937 10s.

The appointment will be subject to the provisions of the County Council's Superannuation Scheme, and the successful candidate will be required to undergo a Medical Examination.

Forms of application and details of duties may be obtained from the undersigned and should be returned not later than first post, November 3rd, 1938.

L. MEREDITH DAVIES,

4, Barnfield Crescent, County Medical Officer.
Exeter.

CITY OF LIVERPOOL. SENIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment at the Alder Hey Children's Hospital, West Derby, Liverpool (940 beds).

Candidates must be single, fully qualified, and registered, and have had considerable experience in diseases of children, and should preferably possess one of the higher qualifications in medicine.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with the usual residential allowances. All fees received in connexion with the appointment to be handed over to the City Council.

The position offers exceptional opportunity for anyone wishing to specialise in diseases of children.

The person appointed will be required to work under the direction of the Medical Superintendent.

The appointment will be made in accordance with the Standing Orders of the City Council and will be determinable by three months' notice on either side.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Applications, upon forms obtainable from the Medical Officer of Health, Hospitals Department, Liverpool, 2, to be endorsed "Senior R.A.M.O." and returned to the undersigned so as to be received not later than Thursday, November 3rd, 1938.

Municipal Buildings, W. H. BAINES,

October 19, 1938.

By Order of the Council.

G. C. ANDERSON, Secretary.

CERN COED HOSPITAL, SWANSEA (Swansea County Borough Mental Hospital.) DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited for the above post from registered Medical Practitioners (male) whose ages do not exceed 45 years.

Candidates must have previous Mental Hospital experience, and must hold a Diploma in Psychological Medicine. Preference will be given to those who have experience as House Surgeon or House Physician in a General Hospital.

Salary £525 per annum, rising by two annual increments of £25 each to £575, with pleasant detached house (rent and rate free), coal, electric light, laundry, and garden produce, which are valued for superannuation purposes at £75 per annum. The appointment will be subject to the provisions of the Asylum Officers' Superannuation Act, 1909, and may be terminated by two calendar months' notice on either side. The selected candidate will be required to pass a medical examination.

Applications, accompanied by copies of two recent testimonials, must be sent to the Medical Superintendent not later than Wednesday, October 26th.

H. L. LANG-COATH,
Clerk to the Visiting Committee

WORTHING HOSPITAL.

Applications are invited for the post of SURGEON to the Hospital.

Candidates must be Fellows of the Royal College of Surgeons of England or Masters in Surgery of a British University. They should not be engaged in general practice, and must reside within easy access to the Hospital.

Applications, with not more than three testimonials (copies only), together with the names of persons to whom reference can be made, should be sent to the Secretary Superintendent of the Hospital, from whom further particulars may be obtained. They should be received not later than October 28th, 1938.

A. V. OAKTON,

October 12th, 1938. Secretary Superintendent

WILSON HOSPITAL, MITCHAM, SURREY. (72 Beds.)

RESIDENT MEDICAL OFFICER, male or female required from November 24th next. Salary £150 per annum, with board, residence, and laundry. The appointment is for six months, renewable for a further six months at the discretion of the Committee.

The Hospital is quite modern and exceptionally well equipped, and carries out work of a character which gives the Resident Medical Officer a considerable amount of experience.

Applications with copies of three testimonials, stating age, qualifications, and experience (particularly anaesthetics), should be sent at once to the Hon. Secretary, "Greenview," Lower Green, Mitcham.

ROYAL SURREY COUNTY HOSPITAL, Guildford.

WANTED, NOVEMBER 1ST,
HOUSE PHYSICIAN AND CASUALTY OFFICER
(Male).

Six months' appointment—recognized for M.D. examination. Salary £150 per annum, with board, residence, and laundry.

Applications, stating age and essential particulars, with copies of not more than three testimonials, to reach the Secretary-Superintendent not later than first post on Wednesday, October 26th.

VICTORIA HOSPITAL, BLACKPOOL (152 Beds.)

HOUSE SURGEON (Male) Required to
Surgical Unit No. 1.

There are four resident Medical Officers. Appointment is for six months. Salary at the rate of £175 per annum, with board, residence, and laundry.

Applications with copies of three recent testimonials should be sent to the
GENERAL SUPERINTENDENT.

ALTRINCHAM GENERAL HOSPITAL. (100 Beds.)

HONORARY SURGEON.

Applications are invited for the post of Honorary Surgeon to the Altrincham General Hospital.

Applicants must have a higher surgical qualification, and should reside within ten miles from Altrincham. Applicants must state what hospital appointments they already hold, and what attendances these appointments entail.

Further particulars and list of duties can be obtained from the Secretary of the Hospital. Twelve printed or typewritten copies of the application, together with three testimonials, should reach the undersigned not later than Monday, October 31st, 1938.

E. A. BIDEN, Secretary.

ABERDEEN ROYAL INFIRMARY.

The Board of Directors invite applications for the appointment of MEDICAL REGISTRAR, to take up duty on or about November 12th, 1938. The post is a resident one and the salary is at the rate of £200 per annum.

Applications, accompanied by six copies of recent testimonials, should be lodged on or before October 24th, 1938, with the undersigned, from whom particulars of the duties and terms of appointment may be obtained.

I, Albyn Place, JOHN A. MCCONACHIE,
Aberdeen. Clerk and Treasurer.

MARGATE AND DISTRICT GENERAL HOSPITAL (95 Beds.)

Applications are invited for the post of RESIDENT MEDICAL OFFICER (male). Salary £150 per annum, with board and laundry. Duties to commence November 1st, 1938.

Applications, accompanied by copies of testimonials, should be addressed to the Secretary at the Hospital as early as possible.

(Appointments continued on p. 59)

AN ANTISEPTIC FOR GENERAL USE AND PRESCRIPTION

Any antiseptic of this nature must necessarily be reliable, safe and of the widest possible application.

Milton fluid, in addition to fulfilling these requirements, is so economical and cheap that its regular use is well within the means of every family household.

Some of the more important characteristics of Milton are:

- (1) It is an "hypochlorite" antiseptic, but contains no chloride of lime.
- (2) It is non-toxic and non-corrosive to living tissues and may be prescribed internally.
- (3) It has a strong germicidal action, even in extreme dilution.
- (4) It is miscible with albumen, dissolves mucus and other proteins and readily penetrates tissues. (Milton is thus excellent for oral irrigation and sterilisation.)
- (5) It is a most efficacious deodorant.
- (6) It is ready for immediate use, is supplied at a standard strength which remains constant.
- (7) It is inexpensive: a 6d. bottle will give protection for nearly a fortnight when used as a gargle twice daily.

Medical practitioners are invited to write for a free professional sample bottle of Milton, and an interesting report, now issued in booklet form, "Report on the Matter of a Chemical, Bacteriological and Biological Investigation of Milton." This will be sent free, together with the sample, on request to Medical Dept., Milton Proprietary Limited, John Milton House, London, N. 7.

MILTON

FOUR POINTS IN HÆMORRHOIDAL THERAPY

The well-recognized value of ANUSOL Suppositories in the medical treatment of hæmorrhoids is the result of a fourfold therapeutic effect :—

- 1 **PAIN IS RELIEVED**—not by the use of opiates or local anæsthetics but by reducing congestion and thus relieving pressure.
- 2 **CONGESTION IS REDUCED**—The emollient, protective and mildly astringent action of Anusol prevents irritation of the affected parts.
- 3 **BLEEDING IS CONTROLLED**—not by means of vaso-constrictors or strong styptics but by reducing congestion and consequent tension.
- 4 **CONSTIPATION IS RELIEVED**—The Anusol base soon melts at normal rectal temperature, softening the hardened fæces, thereby making evacuation easy and less painful.

These desirable qualities distinguish Anusol Suppositories and assure their efficacy in treatment.

Anusol is also available in ointment form in collapsible tube with nozzle.

Supplies for clinical trial sent on request.

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

(B.M.J., 16 Oct., 1937, p. 753)

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamin B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., The Bemax Laboratories (Dept. B.70.), 23, Upper Mall, Hammersmith, W.6.

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertiol.

FERTIOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

A complimentary box of Fertiol Capsules and brochure sent on request.

Vitamins Ltd., The Bemax Laboratories
(Dept. B.70), Upper Mall, London, W.6.

Coramine

'Ciba'

A non-toxic circulatory and respiratory stimulant for oral, hypodermic, intravenous and intracardiac administration, improves the pulse and blood pressure, reinforces the contractions of the myocardium. Increases the respiratory amplitude, activates the ventilation of the lungs causing cyanosis to disappear.

Indicated in collapse, coma, accidents during narcosis, poisoning by coal gas, narcotics and barbitone derivatives, fatigue phenomena, etc.

CORAMINE LIQUID FOR ORAL USE
CORAMINE AMPOULES FOR INJECTION

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega." It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of pain and for replacing hot water bottles.

At all good stores, chemists, electricians; or from Thermega Limited, 51/53, Victoria Street, London, S.W.1.

'Thermega'
Electrically Heated
BLANKETS & PADS

Blankets from 3 gns. Pads from 31/6. 3-Temperature Blankets for medical use, £8 10s. Single-heat Blanket, specially strengthened, from £4 4s. Various sizes and prices on application.

Insist on "Thermega." It is vital that these appliances should be made by experienced manufacturers.

WHITLA'S

DICTIONARY OF TREATMENT

Eighth Edition, by **R. S. Allison, M.D., M.R.C.P.(Lond.)**, and **C. A. Calvert, M.B., B.Ch., F.R.C.S.**, with the collaboration of **H. Gardiner-Hill, M.B.E., M.D., F.R.C.P.**, and **B. W. Williams, M.B., B.Ch., F.R.C.S.**

Pp. 1,286.

Price 30s.

Postage 8d.

Abroad 1s. 5d.

This standard book has long been unique as an encyclopedia of reference for the general practitioner. To its wide and general use the sales of more than 38,000 copies in the seven previous editions give ample testimony. The new edition has been so thoroughly revised and brought up to date that it has the qualities of a new book. It has been entirely rewritten and reset in a new type and format. It remains a book to which the general practitioner can turn for authoritative information on accepted therapeutic methods.

Best and Taylor

PHYSIOLOGICAL BASIS OF MEDICAL PRACTICE. By **C. H. Best, M.D., D.Sc.**, and **N. B. Taylor, M.D., F.R.S., F.R.C.S.**

Pp. 1,684 with 399 Illustrations.

Price 45s.

Postage 9d.

Abroad 2s.

"The book is a storehouse of information lucidly stated and valuable to physiologist and clinician alike. Of the competence of Drs. Best and Taylor for the task undertaken there can be no doubt."

—*British Medical Journal*.

Rose and Carless

MANUAL OF SURGERY. *Fifteenth Edition.* By **Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., F.A.C.S.**, and **John B. Hunter, M.Chir., F.R.C.S.**

2 volumes. Pp. xii + 1,618 with 966 Illustrations. Price 30s. Postage 1s. Abroad 2s. 6d.

"In our opinion the best that has appeared since the last edition by the original authors. We have no hesitation in continuing to recommend this work to students and practitioners."

—*British Medical Journal*.

Feldman

CLINICAL ROENTGENOLOGY OF THE DIGESTIVE TRACT. By **Maurice Feldman, M.D.**

Pp. 1,010 with 358 Illustrations, 179 Tables.

Price 45s.

Postage 9d.

Abroad 2s.

A unique book for the physician, the radiologist and the general practitioner. The whole tract from the oesophagus to the rectum is covered and all pathological conditions of both major and minor importance are fully dealt with in a most practical way.

THERMOVENT

NATURAL CONVECTION ELECTRIC HEATING

provides a warm
healthy atmosphere
at a minimum cost

Heating for the waiting-room calls for convection-type heaters. Thermovent is the only compact and 100% efficient convector and, by virtue of its patented construction, it offers unique advantages:—

- ★ Thermovent warms and circulates the air, giving a pleasant, healthy atmosphere that visitors and patients will appreciate.
- ★ There is no 'radiation' effect and no intense local heat—two feet or twelve feet away the warmth is the same. The element works at black heat—no charring of dust particles and no danger of scorching.
- ★ SPECIAL ELECTRICITY TARIFFS ARE AVAILABLE IN MANY AREAS FOR THERMOSTAT-CONTROLLED THERMOVENT HEATING.

There are inset, portable and floor-standing Thermovents in moulded or steel casings. All types available with built-in thermostat. Prices from £3.12.6. (1 kw). 2 kw and 3 kw types also available.

For full details write to:—

SPENCER BANDEAUX

Are Individually Designed

TO PROVIDE UPLIFT WITHOUT CONSTRICTION

Photograph of Spencer client with pined breasts before her Spencer Bandeau, which had been individually designed for her, was adjusted.

Photograph of the same client immediately after her Spencer Bandeau was adjusted. Note the marked degree of uplift achieved and the well-moulded contour of breasts.

Spencer uplift bandeaux are prescribed for the following purposes:

During pregnancy and for nursing mothers to give support and uplift.

To prevent stretching and relaxation of the skin and supporting tissues of the breasts with consequent ptosis.

To prevent or relieve breast prolapse and aid in treatment of non-malignant nodules and indurations.

The bust packets are made of a slightly stretchy, soft material that permits free-breathing and does its uplift work without

constriction or irritation on the nipples of the breast.

The below-bust section is designed to remain firmly anchored to the figure so that the weight of the breasts cannot pull the back of the bandeau upward on the figure and thereby lessen the degree of uplift that is desired.

Because Spencer Bandeaux are designed and made individually to meet the particular figure needs of each individual patient, they fit perfectly, *remain in place*, and continuously perform the mission for which they are pre-cribed.

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and, because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

To establish a strong positive Iron Balance

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings: 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

The administration of Anahæmin in pernicious anæmia has become a routine as a result of the uniformly satisfactory results produced. Such results are exemplified in a recent report in which it is stated that weekly injections of 2 c.c. of Anahæmin for one month produced an increase in red blood corpuscles from 536,000 to 3,700,000 and a rise in hæmoglobin from 25 per cent. to 60 per cent. At the end of a further six weeks' treatment it was found that the red blood count had risen to 4,600,000, and the hæmoglobin to 70 per cent. This increase in red blood cells from 536,000 to 4,600,000 was produced by a total dosage of 24 c.c. of Anahæmin.

MANDECAL

(Compound Calcium Mandelate B.D.H.)

*In the treatment
of urinary infections*

The superiority of Mandecal over other mandelic acid preparations prescribed in the treatment of urinary infections lies in the fact that, whilst it is equally effective, therapeutically, its administration causes less irritation to the gastric mucosa and eliminates the nausea so frequently associated with this form of therapy.

Furthermore, Mandecal is simple of administration; being miscible with water, it is readily taken in a draught.

Mand. S. r.

In Pruritus Ani,¹ Anal Fissure,¹ Pruritus Vulvæ,¹ and Lower Abdominal Pains originating from the Cervix Uteri²

Proctocaine is a lasting, non-toxic, local anaesthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of A.B.A. Proctocaine is a combination of oil-soluble anaesthetics of low toxicity. These are combined so as to produce *immediate local anaesthesia* which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil-soluble ingredients.

The advantages of Proctocaine over other solutions have been found¹ to be as follows:

1. Its effect is almost certain.
2. It produces anaesthesia or hypo-anaesthesia for periods varying from 7 to 28 days or longer.
3. The relaxation which it produces in the anal musculature is much greater and more prolonged.
4. It is comparatively non-toxic, injection of 20 to 30 c.cm. producing no general effect.
5. Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly.
6. Its injection is painless if made slowly.
7. In no case did it produce severe after-pain.

MARMITE

YEAST EXTRACT
for vitamin B complex
in **POLYNEURITIS**

The close connection between polyneuritis and vitamin B₁ deficiency is well known. Not only is the polyneuritis of beri-beri considered to be due to deficiency of this factor, but so also is the polyneuritis associated with gastro-intestinal lesions, pregnancy, alcoholism and other toxic conditions.

Clinical tests have proved beyond doubt that Marmite therapy is effective in these cases of polyneuritis of nutritional origin. In a recent paper on peripheral neuritis, associated with pyloric stenosis and deficiency of vitamin B₁, it is recorded that the patient

"was advised to take Marmite, 2 drachms daily . . . made a gradual improvement and returned to work . . . still takes Marmite. . ."

(Lancet, May 7th, 1938, p. 1045.)

Special terms for packs for hospitals and welfare centres

IN DEPRESSIVE STATES

In depressive states the suitability of 'Benzedrine' Brand Tablets (β -aminoisopropylbenzene sulphate), as well as the correct dosage, must be determined for the individual patient.

Tentative classifications, however, suggest that the drug is most likely to be of use in conditions characterized by diminution of capacity for activity, and that it is apt to be contra-indicated in anxiety states accompanied by agitation. In depressive psychopathic states, this form of treatment should only be undertaken in an appropriate institution.

Initial doses should be small, ranging from 2.5 mg. (half tablet) to 5 mg. (one tablet). These should be regarded as test doses, and if no effect is obtained from the smallest amount given, the dosage may be progressively increased until a definite effect manifests itself. Careful medical supervision during this test period is particularly desirable.

When the correct dosage has been determined, it may be given two or three times daily, bearing in mind that administration in the late afternoon or evening may interfere with sleep.

*Detailed literature will be sent to medical men
on request*

"ALOCOL"

Colloidal Hydroxide of Aluminium

For Gastric or Duodenal Ulcer

IN view of the increasing adoption of intensive alkaline medication for gastric and duodenal ulceration, the selection of a suitable antacid agent is a matter of considerable importance to the general practitioner.

"Alocol" allows of antacid therapy in a particularly effective, safe and reliable form, and replaces with advantage mixtures composed of sodium bicarbonate, magnesia, bismuth, etc. It does not determine any unpleasant secondary reactions, even when taken in strong doses and over a long period of time.

The powerful antacid effect of "Alocol" is more mechanical than chemical in nature. It acts by adsorbing excess of hydrochloric acid, thus facilitating its elimination. It promptly relieves pain and being non-absorbable is free from toxic sequelae.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W. 7.

Works: KING'S LANGLEY, HERTFORDSHIRE.

M282

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form, being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request.

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety, while the presence of "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

M283

INDICATIONS FOR 'SANATOGEN'.

No. 6.

TUBERCULOSIS

PUBLIC ENEMY No. 5

Since the beginning of the century, the death rate from all causes has fallen by one-third. The death rate from Typhoid has dropped from 113 per million to 6.3 in 1936; that from Influenza from 189 to 109; whilst from Measles the death rate has fallen from over a thousand to under three hundred. In the first five years of the century, the average mortality rate from Tuberculosis was over 1700; in 1936 it was 657—but it still holds fifth place in the list of causes of death in this country.

For these improvements, better sanitation and the raising of the economic level of the poor are mainly responsible. Environmental circumstances are important, but so far as Tuberculosis is concerned, nutrition is evidently the most important factor. An adequate supply of nourishing food constitutes the first line of defence. The food must be ample, digestible and absorbable; and must include a sufficiency of proteins, vitamins and minerals.

'Sanatogen', which is a carbohydrate-free product of 95% pure milk casein with 5% sodium glycerophosphate, has proved itself to have great value in building up the body's resisting power to hostile bacilli. It is easily digested and assimilated, and markedly increases the nutritional value of other foods taken with or after it. It is notably helpful to the debilitated; rejuvenating cellular activity (including that of the white blood corpuscles) and promoting healthy tissue-building.

'SANATOGEN'

*(Trade Mark)**A Brand of Casein and Sodium Glycerophosphate**Sold by all chemists price 2/3 to 10/9*

DOSAGE: For children and adults two teaspoonsful three times daily, or according to circumstances. For infants $\frac{1}{2}$ teaspoonful added to each bottle feed.

The word 'SANATOGEN' is the Trade Mark of Genatosan Ltd., and denotes their famous brand of Casein and Sodium Glycerophosphate. A 'GENATOSAN' product made by GENATOSAN Ltd., Loughborough, Leicestershire.

Clinical samples and literature available on request to

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE.

Pediatricists

approve these purées

A range of Strained Foods giving maximum nutritive values

THE nutritional value of vegetable purées for infants and soft diet cases is receiving the endorsement of the medical profession to a very marked degree.

Hitherto the difficulties and deficiencies of home preparation—inefficient sieving and destructive oxidation—not to mention the tedium and labour involved—have hindered practical application, but the introduction of a complete range of strained foods by H. J. Heinz Co. Ltd. has been universally accepted as the solution of this problem.

H. J. Heinz Co. Ltd., with their exceptional experience in food preparation, have recognised the legitimate possibilities of supplying strained foods of that maximum nutritive value, uniformity and convenience which only good factory practice can achieve.

The vegetable and fruit purées of H. J. Heinz Co. Ltd. are prepared under conditions of the most scrupulous care with special reference to minimising mechanical loss of mineral salts and other soluble nutriment. The edible portions are washed and trimmed and then cooked under light steam pressure until in perfect disposition for comminution by extrusion and cutting. All mineral salts, vitamins and other soluble nutriment are retained, while harsher fibres, if any, are so reduced as to be non-irritant. The raw materials are purchased when and where seasonal and regional conditions of growth are most favourable, and only fresh gathered vegetables of the highest quality are used.

After the straining process the purée is adjusted to a proper solid content convenient for marketing. Absorbed air is removed and sealing *in vacuo* follows in specially prepared enamel-lined containers. The process concludes with high-temperature sterilisation.

AMPOULES

To be used where an immediate result is wished for. Also for continuous therapy if necessary.

Ampoules (1 c.c.) in boxes of 5 and 100

Ampoules (2 c.c.) in boxes of 5 and 100.

SUPPOSITORIES

The suppositories are used as a supplement to the drug by injection. They may be employed alone where it is difficult or impossible to inject.

Suppositories (0.4 gm.) in boxes of 5 and 25.

PELLETS

These pellets are an even more compact form of 'Salyrgan' and are for the express purpose of lengthening the interval between the injections. They maintain a satisfactory diuresis combined with good tolerability.

Pellets in tubes of 20 and bottles of 250

NEW!

ALKA-ZANE

FOR ACIDOSIS

SODIUM POTASSIUM CALCIUM MAGNESIUM

IN THE FORM OF

CARBONATES PHOSPHATES CITRATES

FOR QUICK
AND EFFECTIVE
REPLENISHMENT
OF
THE ALKALI
RESERVE.

The alkaline needs of the body cannot be satisfied by a single alkali, especially when acidosis makes special demands upon the alkaline reserve. The complex mechanism of physiological neutralization could hardly be maintained with one basic substance. Furthermore, the administration of a single alkali in excess may tend to disturb the balanced relationship existing between the alkaline buffers of the organism. Alkalization with Alka-Zane is free from these objections. It may be used in any condition whenever the alkali reserve needs replenishment and support.

Adequate supplies for clinical trial sent on request.

POWER ROAD, CHISWICK, LONDON, W.4

MADE IN ENGLAND

THE HEPATEX LIVER PRODUCTS

The name Hepatex associated with Liver Extracts
is a guarantee of high potency

HEPATEX (ORAL)

A highly concentrated liquid extract, one fluid drachm containing the equivalent of 2 oz. of whole mammalian liver. One bottle contains sufficient for one week's initial treatment or three weeks' maintenance treatment of pernicious anæmia.

Dose: Initial treatment, one fluid drachm, four times daily. Maintenance treatment, one or two fluid drachms daily.

Bottles of 4 ffd. oz. 12/6 each

NEO-HEPATEX (PARENTERAL)

A highly fractionated liver extract for use in the treatment of pernicious anæmia by intravenous or intramuscular injection.

Every batch is clinically tested and approved by independent hospital test before issue.

Dose: In mild cases 1 cc. doses will be found sufficient.

In the average uncomplicated case it will usually be found that 2 cc. given intramuscularly on each of three successive days will produce a satisfactory response, subsequent dosage depending on progress.

In more severe cases larger doses, given intravenously, may be required.

Ampoules. Boxes of 6 × 1 cc. 5/3 per box

Boxes of 6 × 2 cc. 8/- per box

Ampoules. Boxes of 3 × 4 cc. 7/- per box

Rubber-capped bottles of 10 cc. 6/- each

HEPATEX WITH IRON

A combination of Hepatex with Iron. One fluid drachm contains the equivalent of 2 oz. of fresh liver and one grain of metallic iron with a trace of copper.

Indicated in stubborn secondary anæmia.

Dose: One or two fluid drachms per day is in most cases ample.

Bottles of 2 ffd. oz. 8/6 each

LIVERPOOL and LONDON

THE ADVANTAGES OF COD LIVER OIL

as a source of

VITAMIN A and VITAMIN D

In view of the widely varying vitamin content of many liver oils available to the public, it is interesting to note that the British Pharmacopoeia in their most recent Addendum (1936) lay down a definite standard of vitamin content for cod liver oil, and also a definite dosage.

The vitamin content is standardised at not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D per gramme; and the dosage is given as a minimum of 15 minims (a quarter teaspoonful) three times a day. The oil itself is described as "from the fresh liver of the cod."

'SevenSeaS' Cod Liver Oil is extracted on the boat, within thirty minutes of the fish being taken from the sea. It is therefore fresh and easily digested. It is an interesting point of fact that the process of extraction on the boat is impossible with other fish liver oils. 'SevenSeaS' therefore obviates any need to resort to liver oils made from stale and rancid livers.

In its Standard form, 'SevenSeaS' is guaranteed to conform to the standard

vitamin content laid down by the British Pharmacopoeia. For practitioners wishing to administer Vitamin A and Vitamin D in cases where a large fat intake is contra-indicated, 'SevenSeaS' in its 'High Potency' form has a special significance. The vitamin content of this 'High Potency' oil is guaranteed to be four times the Pharmacopoeia standard, and the dosage can therefore be reduced to a few drops only. This is not a fortified oil, but is obtained simply by selection from the oils of the richest livers.

All 'SevenSeaS' Cod Liver Oil is tested and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in Capsules, will be supplied on request.

VOLPAR

Volpar is the new contraceptive which has been formulated in co-operation with the medical Sub-Committee of The National Birth Control Association; it is the outcome of nearly ten years' continuous investigation conducted by University research workers under the direction of the Birth Control Investigation Committee.

Laboratory tests have shown that the active principle of Volpar is the most powerful non-toxic spermicidal substance known.

An article reporting the results of the above-mentioned investigation was published in *The Lancet* of October 15th, 1938, p. 882, and a letter signed by the medical members of the Birth Control Investigation Committee commenting upon this article has also appeared (*Lancet*, October 22nd, 1938, p. 970).

Volpar is issued in two forms:—

VOLPAR GELS

Soluble suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath.

VOLPAR PASTE

Anon-greasy paste for the lubrication of occlusive caps and sheaths or condoms.

Volpar Gels and Volpar Paste are sold only by pharmacists at the following prices (applicable to Great Britain only):

GELS: in screw-capped glass tubes containing 1 dozen gels, 2s. 0d.

PASTE: in collapsible tubes containing sufficient for 12 applications, 2s. 0d.

FORMULA

EACH FLUID OUNCE REPRESENTS:

Calcium Iodide (equivalent to Iodine 6 grs.)	7 grs.
Ephedrine Hydrochloride	3/8 gr.
NEMBUTAL	3/8 gr.
Codeine Sulphate	1/4 gr.
Syrups Wild Cherry and Tolu, with Aromatics	q.s.

FOR COUGHS { *Acts to Liquefy Bronchial Mucus* *Produces Distinct Sedative and Antispasmodic Effects*

Syrup Calcidrine (Abbott) offers, in an unusually palatable and well-tolerated combination, an effective cough sedative with distinct antispasmodic properties. The high iodine content of the preparation, as represented in calcium iodide, distinguishes it from the usual demulcents and expectorants. ● Clinical experience has shown the value of certain combinations of iodine and calcium in the treatment of colds, including simple

throat and bronchial infections of an acute and subacute nature. The iodides are often used to liquefy bronchial mucus and thus to facilitate its removal. There is evidence that they tend to produce an unfavourable soil for the increase of bacteria in the throat and respiratory passages. ● The combined effects, therefore, of iodine and calcium, with the antispasmodic action of Ephedrine and the sedative action of Nembutal, can be utilised to great advantage in the

treatment of acute and subacute bronchial infections, especially where night cough prevents proper rest and sleep. ● Syrup Calcidrine (Abbott) is supplied through pharmacies in 4-oz., 16-oz. and 80-oz. bottles. Literature and a trial sample will be sent upon request.

The Lister Institute
OF PREVENTIVE MEDICINE

Compound Catarrhal Vaccine

In catarrhal conditions of the respiratory passages mixed infections are found more often than pure infections with one type of organism. *Bacillus influenzae*, *Pneumococcus*, and *Micrococcus catarrhalis* are believed to be the commonest primarily infecting organisms, but *Streptococcus* and *Staphylococcus* seem to be responsible for many of the secondary infections. A mixed vaccine has been prepared from these five kinds of bacteria. It is generally given as a prophylactic, but may also be used in acute respiratory infections.

DOSAGE—Prophylaxis: 1st dose, 50 million *B. influenzae*, 10 million *Streptococcus*, 25 million *M. catarrhalis*, 25 million *Pneumococcus*, 125 million *Staphylococcus*. Subsequent doses at intervals of 7 to 10 days, gradually rising to 8 times the original dose. Then 4 to 8 times the initial dose every 4 to 8 weeks.

Treatment— $\frac{1}{2}$ to $\frac{3}{4}$ of the prophylactic doses.

PRICES—Ampoules containing

235 million organisms per c.c., each	2/6
470 " " " " "	2/6
940 " " " " "	2/6
1,880 " " " " "	2/6

10 c.c. rubber-capped vials containing
470, 940 or 1880 million organisms per c.c., each 15/-
25 c.c. ditto ditto, each 25/-

Compound Influenza Vaccine

The Compound Influenza Vaccine prepared by the Lister Institute contains the chief types of bacteria found in the catarrhal secretions of the respiratory passages in epidemic influenza, viz.: *B. influenzae*, *Pneumococcus*, and *Streptococcus*. It is primarily intended as a prophylactic, but may also be used for treatment.

DOSAGE—Prophylaxis: 1st Dose, *B. influenzae* 200 million, *Pneumococcus* 100 million, *Streptococcus* 50 million = 350 million organisms. 2nd dose, 660 million organisms, 7 to 10 days later. In treatment 1/5th to 1/20th of the prophylactic doses may be given commencing with the lower dose in severe cases.

Compound Influenza Vaccine

PRICES—

In ampoules of 1 c.c. containing 330 or 660 million organisms per c.c., each 2/6
In 10 c.c. rubber-capped vials containing 660 million organisms per c.c., 15/-
25 c.c. ditto ditto 25/-

STATES OF DEPRESSION: THEIR CLINICAL AND AETIOLOGICAL DIFFERENTIATION*

BY

AUBREY LEWIS, M.D., F.R.C.P.

Clinical Director and Lecturer on Psychiatry, Maudsley Hospital

Classification and diagnosis have been so derided in psychiatry that the subject of our discussion to-day is almost a shady one. No doubt the shadow under which it lies comes also from the solid difficulties, which are plain when any of the current ways of differentiating between depressions are applied to a series of cases. It is, I think, at all events correct to say that (although a fair amount has been written) no fresh light has been cast on the subject for several years, since it is much easier to show the inadequacy of proposed methods than to substitute for them a useful and valid one. Useful and valid are the two epithets which any classification should deserve. In considering them the opportunities and difficulties can be brought into clearer view.

Valid Classification

The usefulness of a classification will vary according to who uses it. One that serves the clinician well may be of little value to the research worker: it may even make his task harder. The clinician wants classes into which he can put his patient's illness after a reasonably brief period of investigation, and which will assist him to make a prognosis and decide on treatment. So long as the classes do this, it does not matter how illogical, psychologically or pathologically unsound, and expressive of his own idiosyncrasies they may be: they provide him with extra knowledge of the sort he wants, and he does not care whether they represent his own, more or less incommunicable, experience or the fruits of others' study. The man who treats patients only in private practice may find a classification useful which the physician in the mental hospital regards as illusory, and the latter may use one which the consulting-room psychotherapist detests or cannot understand: both these classifications may be useless to the general practitioner. If all three physicians had the same clinical material and problems they would no doubt come to use the same classification; but at present they do not, although they may use the same words for their classes: to realize this one has only to compare the letters sent by each of them when referring depressed patients to an out-patient clinic. Because of the peculiar phenomena of mental disorder, so much harder to describe in agreed conventional terms than those of other illnesses,

it is customary for clinicians to use their words, and their classes, with an individual twist. This is what distinguishes them from those of the research worker. He wants his classes, and his words, to have some fixity, so that he can generalize and summarize and communicate his observations: he cannot work in circumstances where the case that he calls an endogenous melancholia another man may call a reactive depression, and a third man call a paranoid schizophrenic. He may be satisfied if he can delimit a class of depressions in which the only distinguishing feature common to all members of the class is some chemical anomaly, even though for the clinician this turns out to be a woefully heterogeneous group. Many quarrels about the justness of classifications in psychiatry are usually due to these differing needs of the clinician and the research worker. In an ideal state of knowledge the schism would end, but that is still a distant time.

It might seem that validity is here merely a synonym for usefulness. But classifications may be useful for the wrong ends: they may be used to separate off cases which are regarded—wrongly—as hopeless, or as needing a particular type of treatment; the clinician may never come to see how vicious are the uses to which he has been, contentedly, putting his classification. The research worker, on his side, may have delimited classes of which the characteristic is irrelevant to his problem, much as though he were to divide depressives into those with and those without naevi, or those whose parents had hernia and those who had not. A valid classification is one which is not only useful, but useful for sound medical or scientific ends. It is necessary to see how far the available classifications are valid in this sense.

The first task of classification is obviously to recognize the depression itself. This is too often taken to be a diagnostic act. It should be concerned with nothing further than description of the emotional state. Any person who is unhappy, and ill with his unhappiness, may properly be said to be in a state of depression. To lay down other criteria for a depression is to raise fundamental problems. For convenience we may restrict the term to those states of depression in which we cannot discover any other significant illness—for example, schizophrenia, cerebral tumour, arteriosclerosis. But the elimination of these is the second task. It is common ground that depression may be the conspicuous or the only clinical evidence of almost any mental illness at some stage: everyone will

* Read in opening a discussion in the Section of Neurology and Psychological Medicine at the Annual Meeting of the British Medical Association, Plymouth, 1938.

aim at spotting the G.P.I., say, or cerebral tumour, or schizophrenia which hides behind a depressive front. What is more, the psychiatrist cannot dismiss this depressive front as a false one, a screen, but has to consider how far it stands for an independent contribution to the total illness. It is at this point that the clinician's private notion of depression creeps in, bringing confusion. If he regards "true" depression as an endogenous illness, of good prognosis, and itself recognizable, he will be interested to see whether this patient's depression conforms to his notion of "true" depression, in which case, if there is also another disorder present, such as a schizophrenic or an obsessional one, he says, "We have here a mixed picture": or he may regard this depression as the normal response to the abnormal situation created by the concomitant, or screened, illness, and may dismiss it as secondary and rather irrelevant. In short, the moment description is deserted, at the second stage of the classifying process, influences get to work which are often only in part consciously recognized as such by the clinician, though they may greatly modify his decisions.

Hereditary and Environmental Factors

The most popular classification is, on the surface, an aetiological one. It says that there are depressions due to heredity (autonomous, autogenous, endogenous, manic-depressive, cyclothymic, vital, constitutional, are among the words employed) and others due to the environment (psychogenic, exogenous, extraneous, reactive, psycho-neurotic). But this is purely theoretical. We have no means of detecting such causes satisfactorily, except in a minority of cases. Moreover, as theory it is bad. It derives from the days when Nature and nurture could be contrasted in an epigram. It assumes that heredity commonly operates with that high probability of manifestation which we see in Huntington's chorea or the height of sweet peas; and that environment can work on an almost illimitably plastic and responsive human organism. As biology has moved beyond these excessively simple views, and recognizes that hereditary and environmental factors commonly interact, it is reactionary to uphold them in the case of a depressive illness, especially when it is so extremely difficult to determine the relative importance of hereditary and environmental factors in any such case. It is probably true that in some depressions the hereditary factor vastly outweighs the environmental, and that in others the reverse is the case, but to detect such cases we have only dubious means—study of the parentage and sibship, observation of the bodily habit, assessment of the relation between the outbreak of the illness and the external factors which might have conduced to it. In the present state of knowledge these are dubious means when applied to the individual case, though they serve well enough for the analysis of a collection of cases, statistically. The number of cases in which critical and experienced psychiatrists with different theoretical standpoints would be found to agree that the hereditary factors were almost certainly responsible for the attack (or, in the alternative instance, that environmental ones were) is, I believe, so small that the subjectiveness of many of our judgments on this matter can scarcely be gainsaid. There are some cases in which a recent distress seems to account for the depression, which is then properly called a reactive one, but since profound melancholia or mania may likewise ensue upon a sorrow, reactivity does not mean only psychogenesis. The more thorough the analysis that can be made of the life of the patient, and of his responses to circumstances, the stronger is one's inclination to attribute his morbid behaviour mostly to post-natal influences;

genetic studies have the opposite effect. There is no reliable evidence as to the heredity of so-called psychogenic depression; and as for the other varieties, what has been reported does not justify distinctions upon a hereditary basis.

Differentiation by Study of Symptoms

A differentiation that can be made by study of the symptoms is of value to the practising physician. When he sees a patient who has fits it is more convenient for him to run over in his mind the differential points given in the textbook tables than to inquire at length into the previous personality, make an encephalogram, etc. At any rate he tries the short method first, preparatory to further search. If he could similarly separate forms of depression he would not be put off by any uncertainty about causes. I have taken a very recent table of the sort: the author says that the differences between neurotic and manic-depressive depression are usually clearly marked: they lie in the constancy of the depression during the attack; the patient's ability to be amused by a joke; to weep, or to appreciate beauty; his interest in himself and his surroundings, his self-reproach, his good health in the period before or between attacks, and his admission that he is ill. Also it is said that in manic-depressive depression "the patient gets well obviously spontaneously. He has been unresponsive to all therapeutic efforts, and the doctor is never given the impression that he has done anything." Nothing could better illustrate what I said earlier about the personal and partly incommunicable value of the classification which a particular clinician may find useful. The psychiatrist quoted works very satisfactorily with a scheme which to me is useless: when I try to apply it it fails, because the same cases will fall on one count into the left-hand side of the table and on another count into the right-hand side. It is true that when first seen in the outpatient department cases often seem to me to fall readily into one or the other category, but when they are gone into more fully in the course of treatment this facility of classification turns out to have been spurious. And I take it that this is partly because my notions of spontaneous or aided recovery, of variability and responsiveness in the depression, and so forth, are not those of the author of the table. Also it is because of a disagreement about facts: patients with severe self-reproachful depression sometimes weep, sometimes even laugh, sometimes worry about their relatives, are mildly depressed and anxious between attacks, or admit that they are ill; patients with chronic reactive depression may be self-reproachful, incapable of appreciating beauty, and never weep. Moreover, in a series of cases I have lately looked through for the purpose, illnesses that fulfil all these clinical requirements of a reactive depression have occurred preceding an acute mania and a severe involutional melancholia, either as an initial stage or as a previous attack (in my earlier published series the same sequence can be found): some of them have been treated as such psychotherapeutically, and with benefit, in previous attacks. Even this shows only how useless the scheme is to me: not that it is generally useless. Actually it is a question of how many patients fit comfortably into either group, so characterized. As is fairly plain in the series I reported, I find that few do; Curran reaches the same conclusion. I think these groups are extreme types rather than clinical realities: a few others, however, find good reason to hold the contrary view. Clouston, who believed in the importance of a distinction (between "melancholy" and "melancholia"), put the matter quite simply in 1904: "Typical cases exhibiting these two conditions are totally different and distinguishable, and the only excuses for confounding them are that they shade off

into each other, that we have no absolutely definite scientific test to distinguish them, that they are both in many cases the outcome of the same temperament and diathesis, and that they both have something of the same nature, both psychologically and physiologically." These are good excuses. Probably there are genuine differences between cases of mainly hereditary causation and those in which environmental causes predominate, possibly also between cases with different kinds of hereditary causation, but the clinical differences given in such tables as I have mentioned do not at present serve to distinguish them. And it is well to remember, as Newman has recently concluded from his studies, that in many ways what heredity can do environment can also do.

There is another such table which includes bodily features—anorexia, constipation, loss of weight. Muncie has stressed the sleep disturbance. Various writers have thought that metabolic variations, especially in respect of nitrogen and carbohydrate metabolism, occur in manic-depressive depression and not in reactive depression. Such claims have not been substantiated as yet. When classes can be separated which are marked by significant somatic differences, it will have the advantage that trained observers will presumably be able to agree as to the presence or absence of these somatic characteristics in any patient.

In recent contributions to the subject emphasis is variously laid upon periodicity, concomitant depersonalization or anxiety and tension, sleep, personality, heredity, psychopathology, and somatic pathology (Rouart, Muncie, Titley, Schnitzenberger, Brockhausen, Montassut, Anthonisen, Schilder, Armenise, Lorand, Baruk and Gevaudan, Georgi, etc.). But periodicity would be more valuable if it could be demonstrated to be a frequent characteristic, whereas actually it is rare; recurrence is of course a different thing, and may be no more indicative of an intrinsic rhythm, a biological periodicity, than is a series of colds in the head; it may indicate recoverability only. As for the anxiety or tension depressions, they cannot be made to form a homogeneous group, for they have only the phenomena of the anxiety attack in common, all the rest being expressible in terms of mild and severe, or proportions of fear and misery. Personality and heredity have not so much cast light on involutional melancholia as left it in a penumbra. Twin studies should, of course, elucidate the whole problem, but until Dr. Slater's material is published nothing is available on this aspect of the classification of depressive states. Psychopathology is as variable as ever in its voices, and no somatic changes are of sufficient definiteness and constancy to be the basis or the buttress of a differentiation.

Distinction between Reactive and Manic-depressive Varieties

Apart from some English writers, it is difficult in the literature of the last five or even ten years to find support for any sharp distinction between reactive and manic-depressive varieties of depression. But a distinction of this sort is often implied in what is written, especially (if it may be said without offence) in the more elementary presentations, in which an almost entirely hereditary psychosis is kept remote from the "neurasthenia" of year-long neurotics and the mourning and unhappiness of those who have lost something of immense emotional value to them. Moreover, in many writings the intelligibility of the occurrence is taken as a criterion: if the physician can enter into the patient's feelings and understand the illness as the natural outcome of situations in which the patient has been, then he calls it psychogenic or reactive; if he

cannot, then he calls it autonomous (thus Adolf Meyer talks of a "true simple melancholia, or 'unjustified depression'"). No doubt this too is a personally valuable way of reviewing the illness, but it has the disadvantages already mentioned as attaching to such subjective judgments. For psycho-analysts it is out of the question, because of the universally explanatory value of their views and method.

There could be no more convincing evidence of the way classifications epitomize theory, and can be serviceable for very limited groups while worthless to others, than the psycho-analytical classification put forward by Glover. Psycho-analytical work in the field of depression during the last few years (for example, Schilder, Klein) has shed as little light on the topic of this discussion as have published studies in heredity, psychology, or somatic pathology.

It is very probable that all the tables and classifications in terms of symptoms are nothing more than attempts to distinguish between acute and chronic, mild and severe: and where two categories only are presented, the one—manic-depressive—gives the characteristics of acute severe depression, the other of chronic mild depression. I am using acute and chronic as temporal words, and mild and severe as indicating the degree of the overt mental disturbance. This, if recognized for what it is, is a useful division, provided the vulgar error is avoided of thinking that every manic-depressive should get well inevitably and spontaneously, and that every case of reactive depression calls for intensive psychotherapy which, if well given, should bring recovery. It also rather fails to provide for the acute mild and the severe chronic cases, which are numerous.

The danger of these classifications, for the clinician, lies in two directions. First there is the assumption, just alluded to, that when a patient's illness seems to fit into the manic-depressive category there is nothing to be done but to fold one's arms in resignation, or, at most, to employ "reassurance and safeguarding" until he gets better of his own accord; and, alternatively, that if it falls into the other group, psychotherapy, and nothing but psychotherapy, will restore him to active life. Treatment should be based on a knowledge of the patient's constitutional qualities and the stresses he has met, not on a schematic and rigid plan, a short cut to the wrong shop. Secondly, it is dangerous because it says, as one of these tables does, that in reactive depression suicide is "sometimes talked but not attempted." Now and again there appears in the account of some inquest the evidence of the doctor who had concluded that it was "only a neurotic depression," and had his views confirmed by a psychiatrist, who found no sign of a "genuine psychosis." Of course, everyone makes mistakes in assessing the likelihood of suicide, and it is quite possible that in these cases the suicide would have occurred anyhow, since one cannot send into a mental hospital every doubtful case of suicidal risk. And, again, it may be conceded that in the hands of some clinicians this method of assessing the risk of suicide works very well. But it is surely bad when that immensely important question of suicide can be disposed of in the practitioner's mind by reference to a classification that creaks at the joints, and is applied differently by different people. Classifications cannot take the place of experience, or of knowledge of one's patient, of the depth of his despair, and the strength of his impulses.

Involutional Depression

These are the two varieties of depression chiefly dwelt upon in textbooks and articles. Attention is also paid to

involutional depression. Thus, one authority speaks of five varieties: constitutional depression, prolonged neurasthenic malaise, true simple melancholia, depressive delusion with intense fear, and catatonic melancholia (but the last two are, of course, usually involutional, and the first covers Reiss's group of 1910, now swallowed up in the reactive group). It is true that some features common in involutional melancholia are rare in other forms of depression, but since these probably depend on the patient's age and on degenerative cerebral disease (often of the vessels), or on schizophrenic admixture, it does not seem necessary for classification to stress them as such, but rather to use the patient's age as the sole reason for calling the depression "involutional," and to seek for further data which will illuminate the prognosis and treatment.

The necessity for making sure that a depression is not due to G.P.I., pernicious anaemia, or other organic disease is present to everyone's mind. But it is less often remembered that the discovery of hysterical, obsessional, or other psychopathic trends in the patient may be important too. A very depressed young woman may be troubled by the thought that she has injured her child through leaving pins about which he could swallow; the obsessional component in this needs examination. A depression in a patient aged 50 may be accompanied by many hysterical symptoms; if the patient has most of his life shown nothing hysterical in his behaviour the possibility of a cerebral arteriosclerosis must then be reckoned with. Or a depression may be found to have developed in a person of schizoid personality, and to be ushering in a schizophrenia. Depression is a very ready psychic response; hence it cannot be evaluated and pigeon-holed without a survey of the patient's life. It was not for lack of instances to support their view that the psychiatrists of the last century believed that most mental diseases began with a stage of depression.

Conclusion

The classification, or avoidance of classification, which I would propose is: first, to determine whether the depression is severe or mild—melancholia or neurasthenia, descriptively speaking; and, of course, there are many grades. Next, does it depend on physical disease, and, if so, how completely? What happened in any previous attacks? On what discoverable influences does it depend: age; constitutional morbid trends; lifelong environmental factors, recent more acutely disturbing ones? What, in sum, is the presumptive balance of environmental forces responsible for the illness as against inherited ones; and what is the balance between environmental influences that may be modified for the better and those that are irremediable? Has the morbid condition been going on long enough to have, so to speak, established an autonomy, set up bodily and mental habits that are inveterate? Have the patient's character and surroundings worked to his advantage or disadvantage during the illness? These are points to weigh rather than points on which to classify; matters of clinical judgment, not solely of observation. A classification can, however, be built upon them. It is because we have no sure means of distinguishing exactly the numerous causes in each case, and their effects, that we must deny ourselves the ease of a simple classification: I think it is a deceptive ease and a deceptive simplicity. No doubt increasing knowledge will bring an improved, eventually even a stable, classification based on aetiology, and pointing, it may be hoped, to treatment: whether it comes by way of genetics, psychology, or somatic pathology, it will be welcome so long as it is useful and valid.

THE CLINICAL SIGNIFICANCE AND ESTIMATION OF BLOOD VITAMIN B₁

BY

EIRWYN N. ROWLANDS, M.D., B.Sc.

Assistant Director, Department of Clinical Investigations and Research, Royal Infirmary and University of Manchester

AND

JOHN F. WILKINSON, M.Sc., Ph.D., M.D.,
F.R.C.P., F.I.C.*Honorary Physician and Director, Department of Clinical Investigations and Research, Royal Infirmary and University of Manchester*

Vitamin B₁ has been used therapeutically in many diseases, but only in beriberi is there overwhelming evidence of its importance. Therapeutic successes, however, have been claimed in nearly all forms of neuritis; thus, Russell (1936) and others have reported dramatic improvement in patients with subacute combined degeneration of the spinal cord following parenteral administration of vitamin B₁ concentrates. We, however, have failed to obtain such striking responses in a series of patients suffering from the disease in varying degrees of severity, although partial relief was noted in a few; a similar series of patients treated in the usual way with liver extracts or preparations of hog's stomach showed much more satisfactory improvement.

Writers on nutrition differ noticeably in their views of the incidence of vitamin B₁ deficiency; thus, whereas Hutchison and Mottram (1936) state that "it is in the perversity of things that food faddists have raised more to-do about vitamin B₁, which few, if any of us, lack," Vorhaus (1937) and McCarrison (1936) have remarked on the relative frequency of this deficiency, McCarrison writing that "the insufficient ingestion of vitamin B₁ is a common food fault."

Our disappointing results in subacute combined degeneration of the cord, the difficulty of assessing the value of vitamin B₁ in this disease, and the many statements that these patients are deficient in vitamin B₁ led us to investigate the possibility of estimating satisfactorily the state of vitamin B₁ nutrition in a series of normal subjects and in patients. The vitamin B₁ content of a diet is not easily estimated from a list of its constituents, and Williams (1938) considers that it is impossible to do so from the available data with an error of less than 50 per cent. Biological assay and the chemical methods so far employed are not sensitive enough to measure the minute quantities present in blood. Roscoe (1936) attempted to estimate the urinary excretion of the vitamin, using for a test the cure of neuritis in rats, but concluded that the method was of little value, while Harris and Leong (1936) have used the rat bradycardia technique.

Test for Vitamin B₁ in Blood

It appeared possible that a satisfactory test for vitamin B₁ in blood might be based upon Schopfer's discovery (1935) that the growth of the mould *Phycomyces blakesleeanus* was proportional within certain limits to the amount of vitamin B₁ present in the medium. By plotting the weight of mycelium obtained against the quantity of vitamin B₁ added, a smooth curve could be produced, and Schopfer used this as a quantitative test for vitamin B₁ in foodstuffs and animal tissues. We have employed Schopfer's technique and applied it to the

estimation of the vitamin B₁ content of human blood; our method is very similar to that since described by Meiklejohn (1937), details of which were kindly made available to us by Professor R. A. Peters. The test we used was as follows:

Technique of the Method Used

Two series of flasks are set up: (1) *The standard range*, containing medium to which known amounts of vitamin B₁ up to 0.5 μ g. per flask have been added; and (2) a similar range of flasks into which are placed duplicated quantities of 1, 2, and 3 c.cm. respectively of the blood under investigation.

The medium for the standard range of flasks is dextrose (0.556 M), asparagine (0.030 M), magnesium sulphate (0.002 M), potassium dihydrogen phosphate (0.011 M); but only half the amount of asparagine is put into the blood-containing flasks. Oxalated blood is used, and the blood-containing flasks are allowed to stand for several hours to allow the corpuscles to form a firm cake at the bottom. The contents of all the flasks are adjusted to pH 6.5 to 6.7 by adding N/10 NaOH and then sterilized by autoclaving. After inoculation with 0.2 c.cm. of a spore suspension of *Phycomyces blakesleeana* (containing not less than 1,000,000 spores per c.cm.) they are set aside in the dark at a temperature of 20° C. for ten days, when the mycelia are removed, washed, and dried at 110° C. for two hours. The weights of mould in the standard range are plotted against the amounts of vitamin B₁ added and a smooth curve is drawn through the points on the graph. The vitamin B₁ content of the blood can then be read off on this graph from the weight of mycelium obtained similarly with the blood samples. It is unfortunately necessary to construct a fresh graph for the standard range with each series of estimations. Thus, in Case II the standard range was as in Fig. 1.

FIG. 1.—Specimen curve showing weight of phycomyces obtained with known amounts of vitamin B₁.

The weights of mycelia, using 1, 2, and 3 c.cm. of this patient's blood, were 22, 44, and 65 mg. respectively, which from this graph give 7, 7.1, and 7.3 μ g. per 100 c.cm.

Evidence in Support of the Method

In spite of the fact that this method may not estimate the vitamin in its natural state in the blood but possibly only its hydrolytic disintegration products, it appears to give a good estimate of the vitamin B₁ content of the blood. There is much experimental evidence in support of this view: (1) The only factor other than vitamin B₁ that has been shown to affect the mould growth is the concentration of nitrogen in the medium; allowance can be made for this. (2) The addition to the medium of a mixture of the two fission products of vitamin B₁,—namely, 4-amino-5-aminomethyl-2-methylpyrimidine and 4-methyl-5-oxethylthiazol (kindly supplied by Professor A. R. Todd)—permits the mould to grow as effectively as with the vitamin B₁ itself. (3) The addition of vitamin B₁ to blood, at least in small amounts, usually increases the growth of mycelium to the same extent as would be produced by the same quantity of vitamin B₁ in the absence of blood. (4) The growth-promoting factor in blood resembles vitamin B₁ in that it is completely destroyed by heat at pH 9. (5) The growths obtained using 1, 2, and 3 c.cm. respectively of blood give values for the vitamin B₁ content per 100 c.cm. that agree within the limits of experimental error for the test. (6) Meiklejohn has shown that blood from pigeons fed on vitamin-B₁-deficient diets gives much less growth than that from normal pigeons. (7) We have found that blood withdrawn after intramuscular injection of pure vitamin B₁ into a non-deficient subject produces a greater growth of the mould, the increase starting about ten minutes after the injection and falling to normal within approximately one hour.

It is not yet possible entirely to exclude the presence of other limiting factors in blood, but the values given by duplicate estimations correspond reasonably, and the error for the test is apparently less than 10 per cent.

Normal Controls

Having established the fact that this phycomyces test gives a fairly reliable method of estimating vitamin B₁, we determined the standard range for normal blood, taken from healthy members of the departmental staff, who gave figures ranging between 6.5 μ g. and 16.5 μ g. per 100 c.cm. of blood. Meiklejohn obtained a range of 6.5 to 14 μ g. in a series of six estimations on human blood. We have therefore considered the normal range to be 6.5 to 16.5 μ g. per 100 c.cm. of whole blood (Table I).

TABLE I—Estimations carried out on Normal Subjects

Initials	Sex	Age	Vitamin B ₁ in μ g. per 100 c.cm. blood*
A. N.	M	40	7.5
E. P.	F	26	9.5
L. E.	M	29	16.5
B. P.	M	25	7.5 7.0
T. J.	M	31	7.0
W. B.	M	17	8.2
S. C.	M	33	6.7 6.5
E. B.	F	24	7.0

* Each figure is the average of duplicate estimations on 1, 2, and 3 c.cm. of blood respectively.

Vitamin B₁ in Disease

Estimations have also been carried out on a series of patients suffering from a variety of diseases, including those in which a deficiency of vitamin B₁ has been said to be an important aetiological factor (Fig. 2; Table II).

FIG. 2.—Blood vitamin B₁ in normal controls and patients.

Black columns = Deficient patients (vitamin B₁ present in deficient amount). Shaded columns = Intermediate group. Unshaded columns = Normal (vitamin B₁ present in normal amount).

I. Vitamin B₁ and the Nervous System

The study of beriberi and experimental investigations in animals have established beyond doubt an intimate and fundamental relation between vitamin B₁ and the nervous system; it is therefore natural that the vitamin has proved of most value in neurological conditions, particularly neuritis and polyneuritis. It has been claimed that the histological changes in the central nervous system in human beriberi are indistinguishable from those of toxic, especially alcoholic, polyneuritis, but recent work by Davison and Stone (1937) indicates that the pathological changes in the nervous system of rats suffering from inanition are essentially the same as those in animals deprived of vitamin B₁ or vitamins B₁ and B₂; these changes are the same whether the animals are starved with or without the administration of vitamins B₁ and B₂.

ALCOHOLIC NEURITIS

The most striking therapeutic results have been obtained in cases of alcoholic neuritis, and there are now many claims for its efficacy in this condition (Vorhaus, 1937; Jolliffe and Colbert, 1936). Although most of the clinical observations were not adequately controlled, the recent careful investigation by Goodhart and Jolliffe (1938) has confirmed the good results. Moreover, the patients can be cured in spite of continuing the intake of alcohol.

There is considerable evidence supporting the view that this condition is attributable to lack of vitamin B₁ rather than to a specific toxic action of the alcohol on nervous tissue. For example: (a) Alcohol does not hasten the onset of beriberi and actually delays the onset of symptoms of polyneuritis in rats. (b) The clinical and pathological manifestations of alcoholic polyneuritis are strictly comparable to those of beriberi (Minot *et al.*, 1933); transitional cases occur in which more definite symptoms of beriberi develop (Weiss and Wilkins, 1936). (c) There is evidence of dietary neglect in those alcoholics who develop nervous symptoms (Jolliffe *et al.*, 1936; Minot *et al.*, 1933; Alsted and Lunn, 1938). (d) There is evidence of defective assimilation in alcoholics. (e) Storage in the liver is probably defective in alcoholics,

and it has been claimed that the irritant effect of alcohol on the stomach and liver causes vitamin deficiency. (f) There is evidence of increased tissue demand for the vitamin in alcoholics.

TABLE II.—Estimations carried out on Patients with Various Diseases

Alcoholic neuritis appears to be more intimately associated with vitamin B₁ deficiency than any other form of neuritis apart from beriberi: it is relatively very uncommon in this country, and is rarely seen in hospital patients.

One female patient (seen through the courtesy of Dr. F. R. Ferguson), who was known to have taken two bottles of whisky daily for many years, suffered from polyneuritis and Korsakoff's psychosis. Several estimations of the blood vitamin B₁ gave values of only 4 μ g. per 100 c.cm. That the patient's symptoms could be attributed to the deficiency of vitamin B₁ was supported by the marked improvement in both her neurological and her mental condition after the institution of a course of injections of crystalline vitamin B₁ (4 mg.) thrice weekly. She now has a normal vitamin B₁ value of 8 μ g. per 100 c.cm.

NON-ALCOHOLIC POLYNEURITIS

In recent publications it has been suggested that vitamin B₁ acts specifically in cases of neuritis of the most divergent aetiology: Vorhaus (1937) claimed complete disappearance of all symptoms in 90 per cent. of 250 cases, and in 70 per cent. of cases of localized neuritis improvement occurred in spite of the presence of septic foci. He concluded that "the action of vitamin B₁ in neuritis bears a close analogy to that of iron in anaemia." Russell (1936) recorded dramatic improvement in an old-standing case of chronic progressive polyneuritis; similar results have been claimed by many other workers.

We examined three cases of non-alcoholic toxic or infective polyneuritis and found blood vitamin B₁ values of 7, 7, and 9.4 μ g. per 100 c.cm. respectively, which are well above lowest normal values. Treatment, however, with vitamin B₁ failed to produce any improvement.

SUBACUTE COMBINED DEGENERATION

As already mentioned, vitamin B₁ has been claimed to produce very good results, even complete remission, in these cases. We have been unable to confirm this, and poor therapeutic responses in this disease after vitamin B₁ have also been reported by other workers (Sciclounoff and Broccard, 1936; Fouts *et al.*, 1932, etc.). We found that in seven patients the blood vitamin B₁ was normal, ranging between 7.2 and 9.8 μ g. per 100 c.cm.

DIABETIC NEURITIS

Two patients with diabetic neuritis were not significantly deficient (6 and 6.1 μ g.), but a third one had a definitely low blood vitamin B₁ value (4.5 μ g.); this latter patient was in a state of mild diabetic coma.

NUTRITIONAL NEURITIS

Two patients with neuritis due to a definite nutritional deficiency were examined; they showed complete recovery after suitable treatment with normal diet and added vitamin B₁.

The first patient, a woman aged 45, had suffered from neuritis and hyperpæsis for two years; she had complained of flatulent dyspepsia, vomiting, constipation, and anorexia, and had greatly restricted her food intake: in attempts to control the vomiting she never ate eggs, fruit, or vegetables of any kind, and had actually been taking little else but tea and biscuits. There was no evidence of organic disease other than a severe hypochromic microcytic anaemia, achlorhydria, and a subnormal blood vitamin C value (0.16 mg. per 100 c.cm.); her blood vitamin B₁ was the lowest obtained in this series, being only 3.5 μ g. per 100 c.cm. of whole blood. Another woman, aged 48, had complained of paraesthesiae and ataxia for some nine months; she had suffered from long-standing anorexia and was obviously undernourished. There was no evidence of organic disease, but she had a moderate hypochromic microcytic anaemia and hypochlorhydria. Examination showed absence of all deep

reflexes and disturbances of sensation in the lower limbs. Her blood vitamin B₁ was only 4.5 μ g. per 100 c.cm.

II. Vitamin B₁ and Anaemias

In view of the fact that many types of anaemia are essentially nutritional deficiency diseases, and of the probable coincident deficiency of vitamin B₁, the importance of improving the general nutrition of the patient cannot be emphasized too strongly. Nevertheless Davidson (1931), using yeast in a series of different types of anaemia, obtained good results in only one case, while yeast preparations are only in exceptional cases effective in pernicious anaemia, as we also have noted. Wills (1931) found marmite effective for tropical macrocytic anaemia, but as its efficiency is not destroyed by previous autoclaving it cannot be due to the vitamin B₁. Elsom (1937) reported eight cases of macrocytic anaemia in pregnant women who responded to brewers' yeast orally and to liver parenterally; the clinical disturbances appeared when calculations based upon Cowgill's (1934) formula indicated a deficiency of vitamin B₁.

We examined the blood from six untreated cases of *pernicious anaemia* without spinal cord involvement. They formed a representative group of patients with typical uncomplicated pernicious anaemia taken from a series of over 1,000 cases; the blood vitamin B₁ values (7.5 to 9.8 μ g. per 100 c.cm.) were all within the normal range. On the other hand, the blood from three cases of pernicious anaemia with complications gave much lower values, which clearly depend on the complicating disease.

The first patient, a woman aged 61, had a diabetic neuritis (blood vitamin B₁, 6.0 μ g.); the second, a man aged 59 who had been under adequate control and treatment with hog's stomach for three years, had a normal blood count and was suffering from severe furunculosis; his blood vitamin B₁ value was only 5.2 μ g. The third patient, also a man aged 59, had been under treatment for eight years, and although his blood count was normal he complained of a recent and sudden onset of difficulty in breathing with hoarseness and loss of weight: examination showed an inoperable carcinoma of the larynx. His blood vitamin B₁ value was 5.3 μ g. per 100 c.cm.

Three female patients with *nutritional iron deficiency (achlorhydric) microcytic anaemia* had the typical symptoms and signs associated with achlorhydria; their haemoglobin percentages and colour indices were low and they responded completely to intensive iron therapy; the blood vitamin B₁ values were 6, 5.7, and 5.3 μ g. per 100 c.cm. of blood respectively—definitely below the accepted minimum of the normal range. It is well known that this type of patient often shows other concurrent dietetic deficiencies, so that low values for the blood vitamins B₁ and C (Portnoy and Wilkinson, 1938) are commonly found.

Microcytic hypochromic anaemia secondary to other diseases, however, gave normal values, as might be expected in the absence of any nutritional deficiency. Thus three patients, in whom the anaemia directly followed (1) haematemesis from duodenal ulcer, (2) peptic ulceration, (3) severe menorrhagia, had blood vitamin B₁ values of 8, 9.2, and 11.6 μ g. per 100 c.cm. of blood respectively.

Three patients with *malnutrition* had definitely low values for vitamin B₁ in the blood.

Two of these patients were indigent males (aged 62 and 69 years respectively) suffering from very severe scurvy: they were grossly undernourished and neither had taken fresh food of any kind for many months, having eaten only poor quality bread, margarine, tea, and very occasional small portions of meat. They both had most extensive ecchymoses and widespread purpura, particularly of the legs, arms, and face, and haemorrhages from the mucous membranes. Plasma ascorbic

acid determinations showed gross deficiencies (Portnoy and Wilkinson, 1938), in one instance (Case 18) the plasma vitamin C content being less than 0.1 mg. per 100 c.cm. The vitamin B₁ contents of the blood in these two cases were 4.8 and 5.5 μ g. respectively. Both patients responded dramatically to treatment with intravenous administration of ascorbic acid and full normal diets. The third patient (Case 17) in this group had taken a poor diet for many years and was obviously much undernourished, but he did not show any evidence of scurvy; the vitamin B₁ content of his blood was only 4.7 μ g. per 100 c.cm.

III. Vitamin B₁ and Cardiovascular and Kidney Disease

Cardiovascular disorders are common and often important features in beriberi, and there is evidence that the heart returns to a normal condition when adequate amounts of vitamin B₁ are given. Weiss and Wilkins (1936) have reported a series of alcoholic patients displaying severe cardiac failure, which they attribute to an unbalanced food intake, particularly lacking in vitamin B₁; they claim that minor degrees of circulatory disturbance due to vitamin B₁ deficiency are often seen.

During the course of this investigation we did not encounter any patients whose heart disease could reasonably be attributed to a deficiency of vitamin B₁, and our impression is that such cases are distinctly uncommon.

In a woman, aged 67, suffering from essential hypertension, with a normal blood urea and electrocardiogram, we found the blood vitamin B₁ was normal: 6.8 μ g. per 100 c.cm. A second poorly nourished patient, with hyperpneumonia, an enlarged liver, and oedema of the legs, but a normal blood urea, and who had had two previous attacks of eclampsia, had a blood vitamin B₁ of only 5.5 μ g. per 100 c.cm.

A man aged 64 with arteriosclerosis and nephritis had a blood pressure of 135/80, albuminuria, a normal blood urea, impaired renal function, anaemia (red blood cells 3,872,000 per c.mm., haemoglobin 62 per cent., colour index 0.8, white blood cells 8,800 per c.mm.), and a blood vitamin B₁ within the normal range—7.4 μ g. per 100 c.cm. A young man aged 23 suffering from extreme heart failure of obscure aetiology, whose heart was very much enlarged, was found to have a blood vitamin B₁ of 7.5 μ g. per 100 c.cm. After a serious prolonged illness he eventually recovered.

Endocrine Diseases

A few preliminary observations were made on a miscellaneous group of patients with endocrine disturbances, but the numbers are as yet too few to permit deductions to be made. Any changes in vitamin B₁ metabolism are probably secondary to other metabolic disturbances. It has been shown that the need for vitamin B₁ is increased in states of increased metabolism in animals (Cowgill, 1934). Clinical hyperthyroidism, however, is usually associated with increased appetite and the consumption of a well-balanced diet, and only rare instances are accompanied by anorexia. Moreover, the reports of the clinical trial of vitamin B₁ in various metabolic disturbances are conflicting. There is, however, a close relation between vitamin B₁ and carbohydrate metabolism, and changes in the blood vitamin B₁ content in these conditions may be determined by associated disturbances of the carbohydrate metabolism. The following were the observations made:

1. In three of our patients with thyrotoxicosis two had basal metabolic rates of +80 per cent. and +68 per cent. respectively; their blood vitamin B₁ values were subnormal, being 5.4 μ g. and 5 μ g. per 100 c.cm. respectively. The third patient (a woman aged 24) had had five operations on the thyroid gland and still presented the typical symptoms of toxic hyperthyroidism with a basal metabolic rate of +48 per cent., achlorhydria, and a hypochromic microcytic anaemia; her blood vitamin B₁ was 7.1 μ g. per 100 c.cm.

2. A youth aged 19 with eunuchoid infantilism presented the typical appearance of hypogonadism and dwarfism, had a mild hypochromic microcytic anaemia, a basal metabolic rate of -40 per cent., and a normal glucose tolerance; his blood vitamin B₁ was subnormal, being only 5.4 μ g. per 100 c.cm.

3. A woman with very severe Addison's disease who responded dramatically to treatment with large doses of cortin had a blood vitamin B₁ value of 11 μ g. per 100 c.cm. at a time when her blood pressure was 65/55.

Vitamin B₁ Tolerance Tests

The possibility of using tolerance tests for determining vitamin B₁ deficiency has been under investigation, and the conclusions will be published separately. The results so far obtained resemble those of Portnoy and Wilkinson (1938) using vitamin C—that is to say, there is a rapid rise in the blood vitamin B₁ level within the first fifteen

FIG. 3.—Vitamin B₁ tolerance curves.

to twenty minutes after administration of vitamin B₁, followed by a quick fall to normal levels. The pure vitamin B₁ (Aneurin) is given by parenteral injection, intramuscularly for preference, and samples of blood are withdrawn at frequent intervals, the vitamin B₁ being estimated by the method described herein. A disadvantage of these tolerance tests is that relatively large samples of blood must be withdrawn by venous puncture at short intervals—every five minutes for the first twenty to thirty minutes, and then half-hourly.

In Fig. 3 are shown specimen normal curves following the intramuscular injection of 4 mg. pure vitamin B₁ (Aneurin). It will be seen that the maximum blood vitamin B₁ peak occurs about fifteen to eighteen minutes later, and is followed by a rapid fall to normal levels within an hour.

DISCUSSION

Our investigations seem to show that gross vitamin B₁ deficiency is rare in this country. This is not unexpected, since the daily requirement for the normal individual is about 500 international units (1 mg. pure vitamin B₁); vitamin B₁ has a very wide distribution in foodstuffs, and it is therefore almost impossible for the intake to be inadequate with a reasonable diet. This is in marked contrast to the position with vitamin C, the distribution of which is restricted to certain types of food such as fresh fruits and green vegetables; further, vitamin C is required in much larger daily amounts, and is present in the blood in much greater quantities.

Nevertheless, vitamin B₁ deficiency may arise from (1) an inadequate supply, (2) inadequate absorption.

(3) inadequate utilization, or (4) through its destruction in the alimentary tract.

1. *Inadequate Supply.*—It is known that the storage of vitamin B₁ in the body is limited, and therefore a minimal intake is essential to meet the normal requirements; thus the deficiency observed in patients with alcoholic neuritis, severe malnutrition, and scurvy is undoubtedly due to a defective intake of vitamin B₁, and this is probably also a factor in incipient diabetic coma. Excessive vomiting as in hyperemesis gravidarum may lead to loss from the stomach of vitamin B₁ taken in food and the development of a deficiency; this may be the mechanism by which polyneuritis of pregnancy is produced. A normal intake of vitamin B₁ may be inadequate in certain conditions of hypermetabolism such as pregnancy, lactation, and hyperthyroidism, in which increased supplies of vitamin B₁ may be required. Thus the low values in our hyperthyroid patients may be attributed to a failure to meet an increased demand: it is interesting that the patient who gave a normal figure did not show the typical emaciation associated with thyrotoxicosis.

2. *Inadequate Absorption.*—The vitamin B₁ deficiency observed in cases of simple achlorhydric microcytic anaemia may be an impairment of vitamin B₁ absorption, but the part played by the achylia gastrica in this respect is not known, and it may be concerned with some further intermediate chemical mechanism. Many difficulties arise, since in pernicious anaemia and subacute combined degeneration of the cord achlorhydria is almost invariably present, but the blood vitamin B₁ values are normal in the absence of complications, so that there must obviously be other factors of importance.

3. *Inadequate Utilization.*—This is associated with hypometabolism (as shown by some cases of hypochromic anaemia which fail to respond unless thyroid is given with the iron), toxæmias as from chronic nephritis, and infection; the low figure given by the patient with carcinoma of the larynx may come into this category. It is interesting to note that Schopfer and Jung (1937) found less vitamin B₁ in cancerous tissues than in normal tissues. An unbalanced diet, especially an excessive intake of carbohydrate, has long been known to affect the utilization of vitamin B₁.

4. *Destruction of Vitamin B₁.*—The destruction of vitamin B₁ in the alimentary tract could also lead to an insufficient supply of vitamin B₁ being available for absorption, but the conditions under which this might arise are not clear.

It is evident that a vicious circle arises: in many of these deficiencies an inadequate dietetic intake leads to anatomical or physiological changes within the intestine and then to diminished absorption, which in turn leads to further disorder of the intestinal function. Moreover, some balance between the specific nutritional elements, such as iron and vitamin B₁, may be necessary.

THE THERAPEUTIC VALUE OF VITAMIN B₁

The only conditions in which a gross deficiency of vitamin B₁ was found were: alcoholic neuritis, nutritional neuritis, scurvy, and malnutrition, and in these cases marked improvement followed the administration of vitamin B₁ (and vitamin C in the scorbutic patient). A partial deficiency was observed in simple achlorhydric anaemia.

The cases of subacute combined degeneration of the spinal cord gave normal figures, so the poor therapeutic results following the administration of vitamin B₁ obtained by us and other workers are not surprising. Similarly,

in spite of a few sporadic claims for its efficacy, the vitamin has not proved of much value in polyneuritis other than the alcoholic, gestational, and nutritional forms, and this finding corresponds with the values for blood vitamin B₁ found in this series. It appears, therefore, that the changes in the nervous system in these conditions, though clinically similar to those reported in beriberi, are of different aetiology and not associated with vitamin B₁ deficiency. There is no clinical evidence that vitamin B₁ is concerned in haemopoiesis, and this is corroborated by the normal figures given by this test in the uncomplicated primary anaemias.

Summary

1. The Schopfer phycomyces test has been applied to the estimation of vitamin B₁ in the blood.

2. The modified method described can be adapted as a reasonable test for vitamin B₁ nutrition, and appears to be the best method at present available for dealing with the small quantities of vitamin B₁ in the blood, but it is too laborious and exacting in technique to serve as an ordinary routine laboratory method.

3. The range for the vitamin B₁ content of blood in eight normal subjects was 6.5 to 16.5 µg. per 100 c.cm.

4. From our experiments vitamin B₁ was found to be present in normal amounts in the blood of patients with subacute combined degeneration of the spinal cord, polyneuritis (excluding that due to alcohol and malnutrition), pernicious anaemia without neurological involvement before and after treatment, and secondary microcytic anaemia.

5. Gross deficiencies were present in alcoholic neuritis (4 µg. per 100 c.cm.), nutritional neuritis (3.5 and 4.5 µg. per 100 c.cm.), scurvy (4.8 and 5.5 µg. per 100 c.cm.), and malnutrition (4.7 µg. per 100 c.cm.); partial deficiencies were noted in simple achlorhydric anaemia (5.3 µg. to 6 µg. per 100 c.cm.).

We wish to thank those members of the honorary medical staff of the Manchester Royal Infirmary who kindly allowed us to examine patients in their hospital and private practice, and also Messrs. Roche Products Ltd. for kindly supplying the synthetic vitamin B₁ (aneurin) used in this work.

TREATMENT OF BRUCELLA ABORTUS INFECTION WITH FOUADIN AND PRONTOSIL

BY

A. P. THOMSON, M.D., F.R.C.P.

Honorary Physician to the General Hospital, Birmingham

Reports on the treatment of *Brucella abortus* infection with fouadin and prontosil are gradually accumulating. Personal experience during the last year with the five cases here recorded supports the general impression that in the treatment of this disease both prontosil album and fouadin are of value, and that the former may prove to be a simple specific remedy when the patient can tolerate it in moderate doses (about 3 grammes daily) for a week. In view of the tendency to relapse (Case III) it is probably wise to give short intermittent courses of the drug for two or three months after the fever has disappeared.

Case I

A man aged 37, a patient of Dr. W. C. Blackham of Moseley, was admitted to the General Hospital, Birmingham, on August 3, 1937. In January, 1929, he had pneumonia after influenza. Bilateral sterile pleural effusions followed; that on the left side recurred so often that an exploratory thoracotomy was done without effect. In September, 1929, a large abscess emptied itself through the operation wound; its origin was never determined, but it was thought to have tracked from the mediastinum. The sinus did not heal until 1931. He remained well and active until three weeks before admission, when he became febrile (temperature usually about 100° F. at night) and had transient slight pain in the right hypochondrium. Fever persisted at about the same level; there was some sweating at night, and the pulse varied between 72 and 80.

Physical examination was negative apart from flattening of the left chest—a consequence of the illness in 1929. The urine was normal. A radiograph of the chest showed nothing of significance; a cholecystogram was normal. There was slight leucopenia (polymorphs 50 per cent. in a count of 5,000). Agglutinations on August 5 were positive to *Br. melitensis* at 1 in 250, 1 in 500, and 1 in 1,250, but not at 1 in 50 or 1 in 2,500; to *Br. abortus* at 1 in 250 and (feebly) 1 in 500; and negative for the typhoid and Salmonella groups.

A week later without treatment his condition was unchanged, but the agglutination to *Br. melitensis* now occurred at 1 in 2,500 and to *Br. abortus* at 1 in 1,000. On August 13 he was given 1.5 c.cm. fouadin, and the evening temperature fell to 99° F.; on the 16th 3.5 c.cm. of fouadin was given, and his temperature fell to normal. Three further injections of fouadin, each of 5 c.cm., were given at weekly intervals. After both the last two injections he had a rigor and his fever rose to 102° for a few hours; otherwise, apart from a trivial sore throat, his convalescence was uneventful. On September 7 agglutinations to *Br. abortus* and *Br. melitensis* were obtained at 1 in 5,000 dilution.

Case II

For the following notes I am indebted to Dr. M. I. Dick of Alvechurch. I did not see the patient myself, but advised treatment on the telephone.

The patient was a farmer's wife aged 45, and was the only member of the household who drank no milk except in her tea. She felt ill all through January. She was first seen on January 31, when she complained of aching all over. No abnormal physical signs were observed. Temperature 102° F.

During the following week her condition was unchanged, her temperature being round 101° F. in the morning and 103° F. in the evening. On February 7 strong positive agglutination to *Br. abortus* was obtained. The same day

the patient began to take one tablet of prontosil every four hours. Three days later she complained that the tablets made her sick, and as her condition was no better they were stopped, and on the 12th fouadin was given, the first injection being 3.5 c.cm., and every other day afterwards 5 c.cm. On February 14 her temperature began to come down, and by the 18th was considerably lower. By February 26 she was much better, the morning temperature being normal and the evening temperature usually about 100°. The last injection was given on February 26, nine having been administered. On March 8 the patient was up for a few minutes, but was still having a slight evening rise and was feeling very weak. On March 25 she came downstairs.

Case III

A woman aged 61, a patient of Dr. C. Lowe of King's Heath, was admitted to the General Hospital, Birmingham, on May 24, 1938. She had been treated for pulmonary tuberculosis in 1918, but there was no subsequent ill-health. She had three children, one of whom had tuberculosis of the hip. For six weeks before admission she had high fever (between 102° and 103° F.), usually from midday until 10 p.m., when she sweated profusely. Shivering attacks occurred at intervals. Her appetite was poor; she lost weight and was unable to sleep. She also complained of a tongue that had been "sore and swollen."

Physical examination was negative. The pulse was 110. The urine contained a few pus cells, hyaline casts, and streptococci. Radiographs of the chest were normal. The blood count showed a slight simple anaemia and leucopenia (polymorphs 46 per cent. in a total count of 3,800). Agglutinations were positive to *Br. abortus* at all dilutions to 1 in 2,500 and to *Br. melitensis* to 1 in 1,250; negative to the typhoid and Salmonella groups.

From May 28 to June 5 she was given 3 grammes of prontosil album daily; from June 6 to 10 she had 1 gramme daily. The temperature fell to normal on June 2, and remained so (six days after the first dose of prontosil). In hospital the highest fever recorded was 101° on the day before treatment began. On June 15 agglutination to *Br. abortus* could only be obtained up to 1,250; at this date the leucopenia persisted (3,900) at the same level as before treatment.

The patient left hospital apparently well on June 18. A fortnight later she had a recurrence of symptomless fever, which disappeared after a few days' treatment at home with prontosil album under the care of Dr. Lowe. There has been no relapse since.

Case IV

A woman aged 62, a patient of Dr. Jessiman of Malvern. She had had typhoid in her youth, and her gall-bladder had been drained in 1920. She had been subject to migraine all her life. Rheumatic pains occurred in the right shoulder and sacro-iliac joints for a year, and she "had not been quite well" for some months.

History of Present Illness.—She has been feverish for five weeks (temperature at first between 100° and 101° F. at night and about normal in the morning, but during the last five days has been continuously between 101° and 102° F.). There have been profuse night sweats with an unpleasant odour and occasional "shivers," some neuralgic pain in the face and indefinite pains about the body, a little cough but no sputum, but no other symptoms apart from a sense of severe illness. A radiograph of the chest was normal, and the urine was sterile and otherwise normal. A blood count showed a leucopenia (polymorphs 60 per cent. of total count of 3,600). Blood culture proved sterile; the Widal test proved negative to the typhoid group; and the Mantoux test was also negative. A little dullness was found at the right base; subphrenic abscess was considered, but exploration proved negative (Dr. Jessiman).

The patient was first seen on May 24, 1938, on admission to a nursing home, being very collapsed after an arduous journey of forty miles, and having a sense of impending death. Physical examination proved negative. On the evening of

May 25 her temperature was 103° F. and pulse 106. On May 26 agglutination to *Br. abortus* was positive in dilutions of 1 in 250 to 1 in 1,000 (Dr. J. H. Ebbs). Prontosil album (1 gramme daily) was given on May 26 and 27. Subsequently the dose was increased to 1.3 grammes daily until May 31, from which date 1 gramme daily was given to June 6. The temperature reached 103° F. during the first three days of treatment, but then fell rapidly to normal in the next three days; convalescence was rapid and apparently complete. On June 10 (after ten days of normal temperature) agglutination to *Br. abortus* occurred only in dilutions of 1 in 25 and 1 in 50. The blood count on that date was: haemoglobin, 78 per cent.; erythrocytes, 4,500,000 per c.mm.; leucocytes, 6,400 per c.mm. (polymorphs 42 per cent, with slight toxic granularity) (Dr. J. H. Ebbs).

The patient went to Yorkshire for a holiday on June 19. Towards the end of the month she developed symptoms of cystitis with a high temperature (103° F.). Dr. J. MacGowan of Shipley saw her in consultation and kindly wrote to me on July 8: "Clinically her illness has been solely due to the cystitis, and had she not given a history of having had undulant fever this would never have entered my head. The cystitis has reacted well to sodium mandelate, and she has been afebrile for about a week." In a specimen of blood taken by Dr. MacGowan during the acute stage of the cystitis agglutination to *Br. abortus* up to 1 in 2,560 and to *Br. melitensis* to 1 in 320 was found by Dr. J. C. Young of Bradford and also by Dr. J. H. Ebbs of Birmingham. The patient has been well since.

Case V

A woman of 50, a patient of Dr. H. V. Jessop of Burton-on-Trent, was first seen on June 22, 1938. She had led an active vigorous life with no illness of significance until six weeks previously. She then felt vaguely unwell and sweated profusely at night, the sweats having a sour, unpleasant smell. Despite this she went for a holiday to the seaside. On her return her temperature was taken for the first time and was found to be 102° F. The fever persisted and was often highest in the mornings. Physical examination was completely negative. The pulse was relatively slow (88 to 96) and the urine was normal. Agglutinations were positive to *Br. abortus* from 1 in 25 to 1 in 900 (Dr. J. H. Ebbs); negative to typhoid and *Salmonella* groups.

Two grammes of prontosil album were given daily from June 22 to July 2; then for three days 2½ grammes daily. From July 5 she took 1½ grammes daily until the 9th, when the drug was discontinued. During the first five days of this treatment there was high continuous fever (from 100° to 103° F.), with severe headache and pains in the limbs. On June 27 physical examination was still negative. On the 28th the temperature fell to normal, and subsequently was raised at times to about 99° F. until July 6, when the fever ended. Her general condition rapidly improved, convalescence being uneventful. A blood count on June 27, after 10 grammes of prontosil, showed no leucopenia (polymorphs 63 per cent. in a total count of 9,900).

In view of the relapse in Case III I advised that prontosil (1½ grammes daily) should be taken during one week of each of the two following months.

Summary

Five cases of infection with *Br. abortus* are reported. One was treated with foudadin alone with apparent benefit (Case I). It was a mild case, but fever had been continuous for four weeks, and the titre of the specific agglutination rose steadily in the week before treatment began.

Case II took prontosil album (3 grammes daily) for three days without improvement, and as she then began to vomit treatment by foudadin was adopted. Dr. Dick considers that she undoubtedly benefited, and her fever declined considerably in five days, though it did not become normal for a fortnight.

Cases III, IV, and V were treated with prontosil alone, and in all of them improvement was rapid and in the most severe one (Case IV) was dramatic. The temperature fell to normal in all of them in less than a week. In view of the tendency to leucopenia in *Br. abortus* infection the dose of prontosil album used was comparatively small; in none of the cases were any toxic symptoms observed, and there was no increase in the leucopenia found in two of them.

Case III had a relapse three weeks after prontosil was discontinued, but it was rapidly controlled by a further course of the drug.

Case IV had acute cystitis during convalescence; this cleared up under treatment with sodium mandelate.

In Cases II and IV the specific agglutinations declined to negligible titres after prontosil treatment; this was not observed in Case I, which was treated with foudadin alone.

In Case IV the specific agglutination rose again to a high titre during the febrile reaction to the cystitis. Topley and Wilson state: "Agglutinins are generally present in a suggestive titre by the end of the second week, and in frank cases of undulant fever they generally rise to 1 in 640 or over. After the attack is over they tend to fall fairly rapidly, and may sink to a low level within three months. There is evidence that in chronic cases they may fall even during the period of active infection."

It would be interesting to know if a fall in the agglutination titre is common after prontosil treatment.

[Since this article was written Case V had a slight relapse early in September. Fever persisted only three days and was rapidly controlled by prontosil.]

REPORT ON FIVE CASES OF BRUCELLA ABORTUS INFECTION

BY

MICHAEL GAFFNEY, M.B., F.R.C.S.

Honorary Surgeon, Lloyd Hospital, Bridlington

Infection by *Brucella abortus* is uncommon enough in this country to justify the recording of the occurrence and treatment of five cases in one practice.

History of the Disease and its Mode of Spread

Brucella abortus was first identified by Bang in 1897, and it was shown by him to be the cause of contagious abortion in cattle. It was then called "Bang's bacillus." Kennedy in 1914 demonstrated agglutinins for *Brucella melitensis* in milk and serum of cows in London—which cows were no doubt infected by *Br. abortus*. But it was not until 1921 that Bevan, in Rhodesia, demonstrated agglutinins in human serum. Cases were first reported in England in 1928-9.

It is stated by experienced workers that the usual mode of spread of the disease is by infected unpasteurized milk and cream, but it can also be spread by contact with infected animals, their carcasses, discharges, or excreta. It appears that a healthy cow may continue to yield milk which is infected long after all symptoms of abortus fever have cleared up. The disease may also be disseminated by farm hands, butchers, sausage-makers, and veterinary surgeons: the latter's serum often contains agglutinins, though activity of the disease has never been manifest. Infection in such cases is probably latent. Contact from man to man has never been demonstrated (Beckman, 1938).

Account of the Present Series

Symptoms.—In all five cases the onset was insidious. The patients complained of malaise, sweating, bouts of shivering, loss of energy, loss of appetite, and a feeling of lassitude and of being out of sorts, but none of them could fix a definite date for the onset. They mostly said that for several days, and in some cases weeks, they felt off-colour. Headache and pains in back and joints were fairly constant features.

Clinical Features.—What struck me most was that although these patients had very high temperatures—102° to 104° F.—the pulse rate was relatively slow and they neither felt nor looked desperately ill. None of them showed any signs of anaemia, and in one case which relapsed and in which anaemia was suspected the blood count was normal. In two cases there were patches of dullness in the chest which were of a shifting nature. Tenderness over the gall-bladder was common in all cases, though not very pronounced. There was no anorexia, no enlargement of the spleen or of the liver that I could detect, and no diarrhoea; but there was a tendency towards constipation, probably due to loss of fluid from the body owing to sweating. The temperature was usually highest at about 6 to 7 p.m. (102° to 103°) and normal in the morning. Depression was fairly general, and one patient who recovered rather quickly was very depressed for several weeks afterwards. The depression may have been partly due to the sulphanilamide.

Diagnosis.—The clinical features of the disease are so vague and indefinite that diagnosis is extremely difficult. The long-continued fever without any other definite signs may make one suspicious and may lead to a tentative diagnosis; but the malady may be confused with other conditions—for example, tuberculosis, influenza, bronchial pneumonia, or typhoid, as well as tularaemia, infective arthritis, and Hodgkin's disease; hence one has to seek the aid of the laboratory. In fact, it is only by laboratory examination for agglutinins that the definite diagnosis of the disease can be arrived at. It appears that the organism can also be cultivated from blood, faeces, and urine; but this is successful in a small number of cases only. Blood cultures were tried twice in one of my cases without success. This failure is not to be wondered at, since Sir Weldon Dalrymple-Champneys shows only 16 per cent. of successes in his records. In all my cases the blood serum was positive in dilutions of from 1 in 500 to 1 in 2,500.

Treatment.—All the cases were treated with sulphanilamide, starting on the first day with 22½ grains. On the second day 45 grains were given, this daily dose being kept up until the temperature was normal morning and evening. The dose was then decreased for three days, when it was stopped. In four cases the temperature fell to normal in from seven to ten days; but in one case it rose each evening to 100° for fourteen days, and then kept on gradually coming down for another thirteen days before it remained normal. The sulphanilamide was continued throughout that period. The temperature has remained normal since, and this patient has not had a relapse.

Relapses.—Three cases relapsed. Two relapses took place after the temperature had been normal for about fourteen days and one at twenty-eight days. The clinical features were much the same as in the earlier stages, but the patients felt less ill. Sulphanilamide was again given, and after varying periods (three to six days) the temperature settled down once more and has remained normal since.

Complications from Sulphanilamide.—There was only one patient—a woman aged 39—who showed any idiosyncrasy to it. She received 45 grains daily, becoming cyanosed and showing definite congestive symptoms, with marked tachycardia. In her case the drug was discontinued for two days, and she was then given 22½ grains daily. This was the patient who relapsed after her temperature had been normal for twenty-eight days. Other patients complained about being depressed. Their depression was considerably less when the drug was stopped.

Commentary on the Cases

Five cases of *Br. abortus* infection were treated with sulphanilamide, and it is my opinion that the drug had a definite influence in decreasing the length of the disease, the duration of which is said by Sir Weldon Dalrymple-Champneys to vary from three to thirty-nine weeks, with an average of twelve and a half weeks, though I suppose that five cases are too small a number for much reliance to be placed on the success of the drug. The longest period in any case of mine in which the fever persisted continually was four weeks, the shortest two weeks. In the three relapses, when sulphanilamide was repeated the temperature dropped to normal in from three to six days and has remained normal since. The last of these relapses occurred forty-one days ago. It is said by Gatt (1938) that American workers have not found the drug to have had any influence on the course of the disease, but other practitioners (Lloyd, 1938; Matthews, 1938) believe that the drug does shorten the course of the disease. Moreover, the fact that the temperature settled down in a few days in all three cases of mine that relapsed and were given the drug again is fairly good proof of its efficacy.

Their Mode of Spread

In all five cases that came under my notice the milk was obtained from the same dairy. There was also one other case in another doctor's practice; the milk concerned in this came from the same dairy and at about the same time. The first case occurred in my practice on January 14, 1938, the last was detected on May 5. The fact that six cases were seen in a period of less than four months and that all of these patients obtained their milk from the same dairy may indicate either a fairly heavy infection of the herd or a virulent organism. The dairy in question is one of the best in England, and supplies only T.T. milk. The owner denied that any of his herd were suffering from contagious abortion at the time the first case was discovered, but admitted that he had a cow that aborted in December, 1937. He had her removed from the herd shortly afterwards, and since then no cow had aborted or shown any signs of abortion. The milk from the herd was examined in batches by the North Riding Laboratory, Scarborough, but no growth of the organism was obtained. In view of what has already been said, this is not to be wondered at. Since the outbreak in the herd, which is composed of fifty-five cows, all tuberculin-tested, has been inspected by a veterinary surgeon from the Board of Agriculture and Fisheries, and all were found to be healthy and free from any disease of the udder. The question of a human carrier might arise. Needless to say the outbreak caused great alarm to the dairy farmer concerned, as he supplies about 800 bottles of T.T. milk daily to this area, and, moreover, he is one of the chief pioneers of clean milk in the country.

General Commentary

Hitherto only isolated cases have been reported by different practitioners up and down the country; cases

quently five cases in one practitioner's practice must be considered most unusual. The age incidence is more or less in conformity with other people's findings. The sex incidence, however, is well worth noting: I had two males and three females, and another practitioner had one female—that is, four females and two males. Creed states that the relation is two males to one female—mine is the reverse. He also says that the reason why so many males are infected is that they only drink milk spasmodically and not often enough to keep up their immunity. Perhaps it is the females who don't drink milk sufficiently nowadays, in case they lose their figures! There is also one other point: a husband and wife were found to be suffering from the disease. It appears, from what Sir Weldon Dalrymple-Champneys says, that this is the first married couple that has been reported suffering from the disease. They were both ill at the same time. It is said that abortus fever is not transmitted from man to man. Here it may have been. It appears that one attack confers lasting immunity on the individual, and it may be possible that many people become immunized by repeated small doses of infected milk and yet never develop any definite signs of the disease.

I understand that there is a movement afoot by the Board of Agriculture and Fisheries to try to stamp out the disease.

Pasteurization of milk is the only safeguard against abortus fever. This must be done with a proper plant, as home pasteurization, which has been tried by one family, has not been a success, since each member complained that the milk was unpalatable.

I beg to thank Sir Weldon Dalrymple-Champneys for his great kindness and for many helpful suggestions in preparing these notes, and also Dr. Colville, medical officer of health for Bridlington, for reports on the herd and the milk.

G. Frontali and G. Ferrari (*Minerva med.*, 1938, 29, 133) record their observations on fourteen cases of pellagra, five in men and nine in women. Seven had had from one to six previous attacks, and in seven it was the first attack. All had severe attacks with nervous symptoms, and in ten cases psychological symptoms were also present. Three cases were chronic forms with symptoms of dementia, and belonged to families in which other members had had psychoses associated with pellagra. Seven cases showed forms of amentia with depressive manifestations, and two of these were also chronic alcoholics with delirious ideas and visual and auditory hallucinations. All the patients were treated for periods ranging from thirty days (nine cases) to forty or fifty days (five cases) with nicotinic acid in doses of 160 mg., partly by mouth and partly by intramuscular injection. In four cases the treatment was associated with a diet likely to produce pellagra. The results were the same in all cases. There was: (1) complete cure of the pellagrous dermatitis in one or two weeks; (2) resumption of the normal digestive functions and a gain of 5 to 8 kg. in thirty to thirty-two days; and (3) a slow but sure disappearance of nervous symptoms in three or four weeks' time. As regards the psychological manifestations, the three chronic cases with dementia showed no appreciable change, while the others made a complete recovery.

THE SUPPRESSION OF LACTATION BY
ORAL OESTROGEN THERAPY

BY

G. L. FOSS, M.A., M.B., B.Ch.

Colston Research Fellow, 1935-7; Clinical Assistant in
the Gynaecological Out-patient Department, Bristol
Royal Infirmary

AND

P. PHILLIPS, M.Sc., M.D., Ch.B.

Medical Superintendent, Southmead Municipal Hospital,
Bristol

Recent progress in the study of lactation has assigned to the anterior pituitary gland the initiation of yet another physiological process—namely, lactation. A large body of workers have demonstrated that injections of anterior-lobe extracts stimulate lactation in the mammary glands of guinea-pigs, rabbits, ferrets, goats, cats, dogs, sows, cows, and monkeys where previously they have been adequately treated with oestrogens. The literature is very well reviewed by Folley (1938).

It is common knowledge that lactation in the human does not begin until forty-eight to seventy hours after the birth of the child, and is preceded by a gradual engorgement and distension of the breasts, which are stimulated by the mechanical action of suckling; this causes release of the lactogenic hormone from the anterior pituitary (Selye, Collip, and Thomson, 1934). In view of the interrelation and antagonism of the various hormones in the body it is thought that the development of the breasts occurs under the influence of oestrogen and progesterone during gestation. Oestrogen causes growth of the duct system, while progesterone and oestrogen develop the lobule-alveolar system (Nelson, 1936). At parturition, and following the separation of the placenta, the oestrogen-progesterone level falls and the inhibition of the anterior pituitary is removed, with the result that the release of lactogenic hormone stimulates milk formation in the mammary glands (Nelson, 1936).

Clinically this knowledge is of considerable importance from two main aspects: (1) stimulation of lactation; (2) suppression of lactation.

Stimulation of Lactation

This depends upon treatment of cases showing a deficiency of milk secretion with the anterior pituitary lactogenic hormone called "prolactin" by Riddle. So far experiments have almost exclusively been carried out on animals, but Folley (1938) suggests that the extracts used must have contained other pituitary factors. Kurzrok, Bates, Riddle, and Miller (1934) and Ross (1938) claim that there is a slight increase of secretion in women after administration of large doses of prolactin, and that the mothers treated were able to nurse their infants completely on discharge from hospital, whilst the untreated controls had to use artificial feeds. The impurity of the extracts at present available is probably responsible for severe local reactions which follow the injections of the larger doses, and, so far, the stimulation of lactation is of scientific interest only.

Suppression of Milk Secretion

This is a definite clinical application of great importance, but unfortunately it is as yet very little known. Once lactation is established, Folley (1936) has shown, in

the cow, that oestradiol monobenzoate and oestrone concentrate the fatty and non-fatty solid content of the milk. It is suggested that the administration of exogenous oestrin will inhibit the anterior pituitary also and depress the lactogenic principle. Various reports have appeared on this inhibitory action by injections of the follicular hormone in lactating rats (Folley and Kon, 1938; Herold, 1938) and women (Lindemann, 1938; Brea and Gándara, 1937; Adrian, 1938), mostly using quite large doses by the intramuscular route.

It is our object to show that small doses by mouth are perfectly adequate and that a definite advance can be claimed for such simple therapy. Our attention was called particularly to the action of oestradiol benzoate in suppressing lactation following attempts to induce labour and for sensitization of the uterus when the foetus was believed to be dead. It was found that after delivery the breasts were devoid of all secretion of milk.

Case A.—Mrs. H., aged 30, 1-para, was admitted at full term on October 7, 1937. Medical induction at 5 p.m. on October 7 and surgical induction on October 11 failed to start pains. Oestradiol benzoate (progyon) 5 mg. was injected intramuscularly as follows: On October 14 at 7 and 9 p.m.; on October 20 at 12 noon and 4 p.m.; on October 30 at 12 noon, 4 p.m., and 8 p.m. Labour commenced at 12 noon on November 1 of its own accord, and a normal male infant was born at 6.55 p.m. the same day, weighing 6 lb. 13 oz. As a result of this treatment with oestradiol benzoate the breast secretion was absent and the child was put on artificial feeds.

Case B.—Mrs. T., aged 29, 1-para; due May 5, 1937. No movements were felt on March 9, and it was thought that the uterus was becoming smaller. The patient was admitted on March 10, and oestradiol benzoate (progyon) 5 mg. was given the same day. Medical induction was tried on March 11. On March 13, 5 mg. of progyon was given at 2, 3, 4, and 5 p.m. A macerated foetus was expelled at 2 p.m. on the 14th with the cord around the neck five times. Breast secretion was absent.

A case of lactorrhoea was treated in September, 1936:

Case C.—Mrs. R., aged 38, had had three children, the youngest of whom was 2½ years old. She came to hospital on September 23 thinking she was pregnant, as her breasts had swollen and were leaking milk. Her periods had been regular from a month after the last baby, which she fed for four to five months. On June 27, 1936, she had noticed that her breasts had become full of milk, and this condition had persisted since. A sample was expressed for analysis, and was found to be normal human milk. Oestradiol benzoate in doses varying from 5 mg. once weekly to 15 mg. twice a week for periods up to a month effected a temporary suppression only. It was found also that small doses of oestrone (1,000 I.U.) given by mouth frequently had the same temporary effect.

Tage Kemp and Pedersen-Bjergaard (1937), in a paper on absorption and excretion of oestrone, state that "the hormone that is administered orally is rapidly absorbed, and is found for a short time in a fairly highly concentrated form in the blood," but it is also very rapidly excreted. "Nevertheless, since oral administration has many practical advantages it will often be preferred. The hormone must, then, be given divided into as many doses as possible during the course of the day, and so far as is possible in a form that will be absorbed slowly." Accordingly a few cases received oral therapy, using progyon dragees, which contain oestrone and also equilin, equilinin, and naturally occurring lipoids. The number of patients available in private practice was small; consequently a series of cases were collected at

Table showing Case Details

Southmead Municipal Hospital, where facilities were ideal.

The particular indications which made it necessary to suppress lactation are tabulated below, with the number of each type treated in this series.

Stillbirth, miscarriage, or monstrosity	31
Death of child	11
Disease or illness of mother (tuberculosis, disease of heart, eclampsia, etc.)	10
Weaning for adoption or operation	6
Breast abscess	3
Puerperal mania	1

Method of Treatment

The older method of using belladonna plasters has long since been discarded, and at the present time great reliance is placed on the use of saline aperients such as magnesium sulphate, given frequently, fluids being restricted, as well as binding and supporting the breasts. In the large obstetrical unit of Southmead Hospital it has been found that this gives the nursing staff much extra work: for if lying-in treatment is conscientiously carried out the frequent attention with bed-pans is a great trouble, while the use of considerable numbers of sterile pads is an additional expense. At the same time this treatment is distressing to the mother, and may still further weaken a patient whose resistance is already

reduced by a difficult labour. For these reasons such a simple method as oral follicular hormone therapy is welcomed.

In the beginning two doses of five dragees each were given twice daily. The preparation used was progynon (Schering), and each dragee contained 1,000 I.U. of oestrone. In many cases this dose was found to be sufficient, and rapidly all engorgement of the breasts had ceased and the patients became much more comfortable. Sometimes the treatment was continued for two to six days. Later, with the idea of keeping up a continuous supply of inhibitory hormone, five doses of two tablets each were given two-hourly throughout the day, while some patients received one dragee hourly during the day, and also during the night if they were awake.

Results in sixty-two cases have been consistently satisfactory. The ideal method is to start treatment soon after delivery, giving two doses of five tablets each on the first day, following with five divided doses of two tablets each, two-hourly, on the succeeding day or days if necessary. If treatment is not begun until the third day, or later still, it may be necessary to continue two tablets two-hourly for two to four days. No fluid restriction or aperients are necessary, and even binding of the breasts may be omitted in most cases, the support of a brassiere being adequate. The average effective total dose is twenty to thirty tablets, which for hospital practice represents a cost of approximately 3s. to 4s. 6d. It may be argued that magnesium sulphate is much cheaper, but this is offset by the saving in nurses' time and the cost of sterile dressings, whilst many patients who have experienced both forms of treatment for the suppression of milk have no hesitation in their preference for this oral therapy. The nursing staff are most enthusiastic about the method, which has reduced their labours and at the same time relieved many mothers of anxiety and distress.

Later in the period of lactation this therapy has been found of great value for breast abscess. It is suggested that by suppressing lactation at the onset of engorgement and congestion, with attempts at localization, the duration of the case is shortened considerably, and, if an abscess forms, this can be dealt with much more easily in the absence of active milk secretion. The most noticeable effect is the rapid softening of hard, swollen, congested breasts, with almost immediate relief of discomfort; but if the tablets are given immediately after parturition the breasts remain soft and comfortable. However, some milk may be forcibly expressed for many days, and complete disappearance of all milk in the ducts may take some time.

The dosage found to be effective in this series of sixty-two cases was:

- 5 tablets b.d. for 1 day, successful in 26 cases.
- 5 tablets b.d. repeated for 2 to 3 days, successful in 21 cases.
- 2 tablets every two hours in 5 doses for 1 to 4 days, successful in 12 cases.
- 1 tablet hourly in 10 doses for 2 to 3 days, successful in 3 cases.

The time after the birth of the child when treatment was begun is here shown:

Time	Patients	Time	Patients
1st day	9	11th day	1
2nd	16	12th	2
3rd	10	16th	1
4th	9	5th week	1
5th	3	11th	1
6th	1	12th	2
7th	2	13th	1
8th	1		
10th	1		

Breasts were comfortable and soft in two days in eighteen patients, in three days in nineteen, and in four days in fifteen (a total of fifty-two); whilst, of the remain-

ing ten cases, in five days two were comfortable, in seven days five, and in six, ten, and eleven days one each. Thus fifty-two cases (84 per cent.) were comfortable within four days, and in the remaining ten cases a marked relief in tension was noticed but the breasts did not regain normal comfort until a few days later.

Discussion

Experience in a few cases of acromegaly and thyrotoxicosis when attempting to inhibit anterior pituitary function in human beings (Foss, 1937), together with Zondek's statement (1936) regarding the quantity of oestrogen necessary to retard growth and gonadotropic function in rats, makes it difficult to realize that oral oestrone in doses of 20,000 to 30,000 I.U. given over a period of two to six days can inhibit a function of the anterior pituitary. Normally this is only held in check by massive amounts of oestrogen and/or progesterone in the placenta. It is much more possible, in our view, that oestrone acts specifically on the mammary gland, in some way preventing the action of the lactogenic hormone of the anterior pituitary, or even by a direct antagonism to this lactogenic hormone. At present an explanation of this clinical finding cannot justifiably be ventured. It is unlikely that such small doses will in any way influence the chemical constitution of human milk.

We should like to acknowledge our thanks to Dr. S. J. Folley for his helpful criticism, to Dr. R. H. Parry for facilities for carrying out much of this research in the Southmead Municipal Hospital, Bristol, and to Dr. Neumann of Schering, Ltd., for samples of "progynon" dragees which were supplied for the early cases.

The National Smoke Abatement Society (Chandos House, Buckingham Gate, S.W.1) has published under the title of *Britain's Burning Shame* a survey of the ravages caused by atmospheric pollution. This pamphlet, with profuse illustrations, is presented in simple terms. A foreword by Professor John Hilton emphasizes that smoke, which he describes as aerial sewage, is not a necessary evil. Emphasis is placed upon the ceaseless fight of women against dirt and dust, much of which results from the smoke-laden atmosphere in which the majority of the population is compelled to live. The bare facts here marshalled in simple fashion present a dramatic picture of the smoke menace, which competent authorities have estimated costs us not less than £40,000,000 a year. The smoke pall over towns and cities, often shutting out at least half the sunlight, encourages in children diseases of darkness like rickets. The tarry matter and acids contained in the soot increase the sufferings of those affected by respiratory diseases as shown by the increases in deaths from these diseases during periods of protracted fog. Added to this is the psychological effect upon hundreds of thousands of the population who live in conditions approximating to perpetual gloom.

Clinical Memoranda

Cure or Relief of Cases Misdiagnosed "Angina of Effort"

The diagnosis of angina of effort is by no means easy in every case. The symptoms of fibrositis may simulate it very closely, not only symptomatically but in their response to nitroglycerin.

The curable cases referred to here are those of fibrositis of the chest wall with pain resembling angina, and are relieved immediately by trinitrin tablets. The practitioner labels these cases angina because they are relieved by trinitrin, forgetting that Sir William Gowers used to treat brachial neuritis (that is, fibrositis) with liquor trinitrini and tincture of gelsemium.

The treatment of cases in which the pain is due to fibrositis consists in breaking up the nodules with the fingers, using considerable force. The method is very painful, but after four manipulations the pain is much less. In every case that is diagnosed angina the practitioner should carefully search for nodules or painful areas under the clavicles and over the sternum and costosternal joints. Even if these are not found or a grating sound is not elicited fibrositis is present if there is abnormal tenderness or pain on pressure. To find the nodules most easily the fingers should be placed at right angles to the skin of the chest wall as if they were clawed, and be moved up and down the chest wall. Where the nodules are felt and where tender places are found the whole of the chest, back and front, should be treated, using considerable pressure. This should be done not less than four times a week—once a week would be useless—for eight treatments, and if necessary be repeated after an interval of a fortnight. Sometimes it is difficult to find the nodules or the tender points at the first attempt.

Perhaps these cases of pain in the chest may account for some of the 11.6 per cent. of those referred to by Dr. Geoffrey Bourne and R. Bodley Scott (1938) in which no cardiovascular cause could be found. In my practice I have come across four cases in two years. In all of them the pain was felt chiefly on walking.

CASE I

This patient, a man aged 59, had had acute pain in the chest and the left arm for ten and a half months. In August, 1936, he had taken on an average nine trinitrin tablets daily—that is, a total of 279. Treatment was begun on September 1, 1936, and after four manipulations the daily average of trinitrin tablets taken was one. During the last eighteen months he has had only two tablets, and forty in all since the treatment was begun. The blood pressure, heart, and electrocardiograms were satisfactory. This was a case of fibrositis without heart abnormalities.

CASE II

This case, that of a man aged 65, was diagnosed in July, 1936, as angina. The blood pressure was satisfactory, and nothing of consequence was observed in the cardiovascular system. Electrocardiograms were normal. In October 1 began treatment, two series of eight being given. Since March, 1937, he has not had to take trinitrin tablets. A case of simple fibrositis with no cardiac abnormalities.

CASE III

Previously seen by his doctor, this patient, a man aged 53, had had his case diagnosed as angina. When I saw him his blood pressure was 240/135 mm. Hg, and his electrocardio-

grams were not normal. In this case I made three examinations before I found fibrositic nodules. The patient has had some twenty-four treatments, and can now walk a few miles. Formerly, though having to go less than half a mile to his work, he had to take a trinitrin tablet and often to travel by taxi. This patient never takes trinitrin now when walking or working. This was a case of fibrositis with cardiac abnormalities, but the pain was apparently due to the fibrositis.

CASE IV

This patient was a woman aged 60 whose heart was apparently normal. No electrocardiograms were taken. Her blood pressure was 240/120. She has had sixteen manipulations and never has to take trinitrin. Evidently in this case the pain was due to fibrositis.

CASE V

A colleague of mine to whom I had spoken of this condition tells me of a lady aged 55 whose case was diagnosed as angina and coronary thrombosis. She was continually having pains, and her husband had been given a gloomy report of her condition. She was sent to a nursing home in October, 1937, and was there six weeks. She remained most of the time in bed at home until July, 1938. This time my colleague, remembering our conversation, looked for and found fibrositis and himself gave her ten treatments. She is now well and free from pain. At one time she took six tablets of trinitrin a day. Hers was a case of coronary thrombosis, but the pains were due to fibrositis.

The first four of these patients are all able to continue at their work.

Conclusions

1. Certain cases with pain in the chest resembling angina of effort, and relieved by trinitrin, are curable. They are not cases of angina, yet are diagnosed as such. Sir William Gowers confirmed the relief trinitrin gives in some cases of brachial neuritis (fibrositis). These are cases of fibrositis without heart abnormalities.

2. There are other cases presenting heart abnormalities (high blood pressure, electrocardiographic changes, etc.), yet the pain is due to fibrositis. If treated the pain on exertion disappears.

3. Fibrositis should always be looked for when the blood pressure and the cardiac system are normal, even if the symptoms resemble angina of effort and the pains are relieved by trinitrin tablets.

4. Diagnosis of angina is serious for the patient: it may bring his work to an end and cause great anxiety to his family. By the treatment described the patient may be relieved if the case is one of simple fibrositis, and the pain disappears in those cases with cardiovascular lesions in which fibrositis is the cause.

5. The doctor should either perform these manipulations himself or carefully supervise them, and so minimize the risk of failure.

REFERENCE

Bourne, Geoffrey, and Scott, R. Bodley (1938). *British Medical Journal*, 1, 55.

We have received the fourth number of the ninth volume of the *Index to the Literature of Food Investigation*, dated March, 1938, which deals with papers received between October 1 and December 31, 1937. It is announced that in future each annual volume will be issued in four quarterly numbers, dealing respectively with papers received up to March 31, June 30, September 30, and December 31. Copies of the latest issue may be obtained from H.M. Stationery Office, London, W.C., price 4s. 6d.

Reviews

BRITISH MOSQUITOS

The British Mosquitoes. By J. F. Marshall, C.B.E., M.A., F.R.E.S. (Pp. 341; 172 figures, 20 plates. 20s.) London: British Museum (Natural History). 1938.

Mr. J. F. Marshall's *British Mosquitoes* takes the place of Dr. W. D. Lang's *Handbook of British Mosquitoes* published eighteen years ago by the Trustees of the British Museum and now out of print. The main purpose of the present work is to bring together all the accumulated information regarding British mosquitoes, and especially to provide up-to-date descriptions and methods for identifying these insects in all stages of their development. Apart from the entomological point of view, it is essential in the interests of public health that we should have this complete and up-to-date work of reference so that the identification of our mosquito pests can be made with accuracy. Accurate identifications mean avoidance of unnecessary labour and expense in control operations.

The collection, selection, and arrangement of the material for the volume have been done logically and successfully. The chapters begin with "How to recognize a mosquito" and pass on to descriptions of external and internal anatomy of all stages. Next comes the main portion, devoted to detailed descriptions of the British species, together with an account of their breeding places and habits. These chapters are well illustrated by photographs and by clear diagrams of diagnostic features. The synoptic keys to species, both for adults and for larvae, are extremely useful for rapid identifications. The final chapters contain information regarding "control," some general remarks on biology, and notes relating to malaria in Britain.

We learn that there are twenty-nine different species in Britain, though not all require human blood as food. The problem of the man-biting and man-ignoring species of the genus *Culex* is discussed in some detail. Entomological literature frequently records that the common mosquito, *Culex pipiens*, rarely, if ever, attacks man, and yet this mosquito has, on many occasions, been accused of causing annoyance to man. Recently it has been shown that two distinct species have been confused under the name *pipiens*. This name is now reserved for the man-ignoring form and the name *molestus* for the man-biting form. Very little is known about the life-history of *molestus* under natural conditions. What is known has been in great part due to investigations made in response to inquiries from medical officers of health and general practitioners; otherwise, this mosquito has been studied only in the laboratory.

Another recent discovery, that *A. maculipennis* is divisible into several "races," is discussed in so far as it affects Britain, where only two of the "races" are found. This discovery helps to solve some of the problems relating to the distribution of malaria, particularly the phenomenon of the disappearance of the disease from an area, though anophelines are still present in large numbers. "The almost complete disappearance of ague (*i.e.*, malaria) from England is only now commencing to be satisfactorily explained." Fortunately, cases of mosquito-borne disease in Britain are now hardly ever recorded, so that suppression or control of mosquitoes in this country is called for not because they are disease carriers but because of the nuisance and annoyance they cause by

their bites. Breeding places and conditions (well illustrated and described) are so different for different species that Mr. Marshall rightly stresses the importance of accurate identification of the offending mosquitoes before starting measures for control. He points out that haphazard scattering of larvicides may do untold harm. He says: "To apply antilarval treatment to innocuous collections of water, while the inhabitants of the district are being bitten by mosquitoes coming from some neighbouring wood or from a coastal marsh two or three miles away, is not only a waste of public money but also diminishes confidence in mosquito-control work generally."

Throughout the book the author indicates where fuller information on related subjects can be found. For instance, in his chapter on control he rightly considers that descriptions of methods, materials, etc., employed in mosquito-control work would be out of place in a book of this nature, and the reader seeking further details is referred to the relevant literature; references to recent studies in insect physiology also occur, but consideration of such advanced work is purposely omitted as being beyond the scope of the present volume. A bibliography containing some two hundred references and an adequate index round off a volume that will be constantly consulted by many whose work includes the investigation of complaints of annoyance caused by mosquitoes.

ENCYCLOPAEDIA OF MEDICAL PRACTICE

The British Encyclopaedia of Medical Practice, including Medicine, Surgery, Obstetrics, Gynaecology, and other Special Subjects. Volume VIII: Leukaemia to Mucous Colic. Under the general editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. (Pp. 664 (and 48 pages of index); 52 figures; 13 plates, many in colour.) London: Butterworth and Co. 1938.

The eighth volume of the Encyclopaedia opens with an excellent review of the subject of leukaemia by Dr. Janet Vaughan. In the absence of known aetiological factors, a classification according to the morphology of the blood cells is the most convenient. But the process may begin with a riotous profusion of growth of cells from any stage in blood development, though there are three main types—leukaemias dependent upon hyperplasia of the reticulum of the bone marrow, of the lymphoid tissue, or of the histiocytic cells of the sinus reticulum. All these may occur in an acute or in a chronic form, and not all the leukaemias show abnormal numbers of cells in the circulating blood. These varied types are described and illustrated. Lung diseases in their various aspects occupy an important place in this volume: collapse, circulatory disturbance, infections and their after-effects, and tumours; while there is a useful section on post-operative complications, ranging from bronchitis to lung abscess and pulmonary embolism. Liver disease, too, is dealt with in a series of articles preceded by a summary of liver-function tests. French authors have found the distribution of cholesterol and its esters in the blood a useful guide to liver efficiency, but no test, as Dr. Aitken points out, can do more than assess one of many aspects of liver function. Sir Leonard Rogers clarifies the position of tropical liver in medicine, and Sir Rickard Christophers contributes a full and informative study of malaria, not only the medical aspects being dealt with but also the important problems of parasitology and prophylaxis.

Other system diseases included in this volume are those of the lymphatic glands and vessels, the mediastinum, the motor neurone, and an important contribution on men-

diseases in which Mr. Rock Carling discusses diseases of the lips, tongue, jaws, and palate. Sir Arthur MacNalty's broad discussion of the problems of maternal mortality covers the progress that has been made by private and Government interest in the subject, the improvement of training and of the status of midwives. He emphasizes that the evidence available shows that the maternal mortality, which has been reduced considerably (from 19 per 1,000 live births in the middle of last century to 4 per 1,000 at the present day), and which compares not unfavourably with that of other countries, is capable of further reduction. The prevention of maternal mortality is, however, a complex task, a problem of public health as well as of obstetrics.

As in former volumes, the editors have included articles on general subjects of medicine: the growing relationship of it to the law makes it necessary for the medical practitioner to have at hand reliable guidance on his conduct in relation to the world outside his practice. In this volume there are commendable articles on the functions of the medical witness, his conduct and evidence in courts of law; the duties and responsibilities of a medical examiner in medico-legal matters; the notification of criminal cases, of births and deaths, of infectious disease, of mental illness, and of notifiable industrial diseases; claims for compensation for accident and diseases under the Workmen's Compensation Act, 1925. The other subjects dealt with maintain the high standard which has been set in those volumes of the encyclopaedia which have already appeared.

INJURIES TO KNEE LIGAMENTS

On the Injuries to the Ligaments of the Knee Joint. A Clinical Study. By Ivar Palmer. Acta Chirurgica Scandinavica, Volume LXXXI, Supplementum LIII. (Pp. 282: 97 figures. No price given.) Stockholm: Tryckeri Aktiebolaget Thule. 1938.

Though it may appear illogical to separate ligamentous injuries of the knee from meniscus injuries and intra-articular fractures, there is something to be said for directing attention to this group of injuries that seems to have escaped systematic study. There is hardly any aspect of meniscus injury that has not been thoroughly investigated by British surgeons, and yet, somehow, we have neglected injury of the ligaments of the knee. Dr. Ivar Palmer of Stockholm has written a remarkably complete work based on a study of fifty-eight cases, and he has dealt with the subject from every point of view. It must at once be said that his monograph does not make easy reading. In the first place, 280 pages is a generous allowance for so small a group of injuries, and the approach is such that one cannot gain anything by skimming through the author's paragraphs of careful observation and close reasoning. It is almost impossible to give an informative précis of his work. The monograph is written for the studious specialist.

So far as diagnosis is concerned, one method demands our immediate attention. Palmer believes that the injection of radio-opaque fluid into a joint to demonstrate intra-articular abnormalities is now no longer an interesting clinical experiment. In his hands it is an established method, and his pictures are superb. If anyone doubts the possibilities of this aid to diagnosis he should look at Figs. 71 and 72, the first showing normal cruciate ligaments and the second a gap in the anterior ligament. Arthrography shows not only such intra-articular derangements, but a tear in the capsule is revealed by leakage into the soft parts around the joint. Pellegrini-Stieda "disease,"

although discussed in full, is assigned the unimportant place that it deserves. It is possible that there may be more than one cause for the curious sickle-shaped shadow found in the region of the medial femoral condyle, but there is no doubt that in most cases it is due to bone formation in or about the internal lateral ligament, and that it is a late and often symptomless result of injury.

To British readers the advocacy of open operation for a number of ligamentous injuries will come as a shock. It is agreed that the immediate results of conservative treatment, in injuries to the cruciate ligaments, for example, are on the whole satisfactory. But, asks Palmer, what about the late results? The findings at operation show that anything approaching adequate natural repair is often out of the question, and this is bound to prejudice the late results of conservative treatment. Operative repair is therefore advised. Unfortunately Palmer does not proceed to the necessary proof of his contention, for his cases treated by operation are too recent for him to show the superiority of the late results over those obtained by conservative means. It must never be forgotten that theoretical excellence is no guarantee of the success of an operative procedure, and, conversely, there are many methods, shockingly unsound in theory, that yield splendid and permanent results in practice.

DYSMENORRHOEA

Dysmenorrhoea: its Aetiology, Pathology and Treatment. By Albert A. Davis, M.D., Ch.M., F.R.C.S. (Pp. 254; 34 figures, including a coloured frontispiece. 12s. 6d. net.) London: Oxford University Press. 1938.

Though dysmenorrhoea is one of the commonest gynaecological disorders, and one in explanation of which theories have been propounded for centuries, Mr. Albert Davis has made what is perhaps the first really serious attempt to correlate the existing ideas on the subject. That he has approached his task with great thoroughness may be judged from the almost wearying sequence of references—numbering over five hundred and fifty in all—which the reader encounters on practically every page. Beginning with a historical survey of considerable interest, the author deals with every aspect of his subject, even devoting one whole chapter to "nasal, vicarious, and dermatitic dysmenorrhoea." In view of his belief in the neurogenic theory of the aetiology of dysmenorrhoea, it is perhaps not remarkable that Mr. Davis has devoted a quarter of his book to this subject. But his claim that the theory "is based on a sound theoretical foundation, has the advantage of reasonable clinical and pathological proof, has provided the rationale for sympathectomy, and is, moreover, strongly supported by the results of that operation," may be disputed by some clinicians and pathologists, and might even be challenged by the judicially minded reader after careful weighing of the evidence submitted by the author himself in support of his claim.

The anatomy of the autonomic system is admirably dealt with, as also is the technique of alcohol injection in the pelvic plexuses; but the indications for pre-sacral neurectomy, while pathologically concise, are too indefinite to be of practical assistance to the clinician. The author's analysis of the results of this operation is rather indefinite, despite the fact that with characteristic thoroughness he has reviewed all the published reports up to 1936. In claiming 50 to 75 per cent. of cures in carefully selected cases treated by sympathectomy, Mr. Davis makes no mention of the size of his series, though knowledge of this fact is essential to the reader if he is to assess the true value of the statistics.

The part of the book dealing with the histopathology of the pelvic autonomic system contains most excellent photomicrographs beautifully reproduced and clearly illustrating the points described in the text. The neuro-genic theory largely depends for its pathological proof on the interpretation of these sections. The opinions expressed by Mr. Davis may be perfectly correct; but if, in order to distinguish the pathological from the physiological, it is necessary to assess quantitative changes, the sceptic must be pardoned if for the time being he considers the case for this theory as "not proven."

For all interested in the theory and practice of gynaecology this book contains a wealth of useful and concisely arranged information on all aspects of the difficult subject of dysmenorrhoea.

NEURORADIOLOGY

A Textbook of Neuroradiology. By Cecil P. G. Wakeley, D.Sc., F.R.C.S., and Alexander Orley, M.D., D.M.R.E. (Pp. 336; 229 figures. 25s. net.) London: Baillière, Tindall and Cox. 1938.

The application of radiographic technique to the localization of cerebral and spinal tumours has developed so rapidly of recent years that it is surprising to learn that no book has hitherto been published which deals with this subject as a whole. The *Textbook of Neuroradiology* by Mr. Wakeley and Dr. Orley will go far to fill this gap. Its most valuable chapters are those dealing with the methods which have been devised to demonstrate the foramina in the base of the skull and the exact position of cerebral tumours as shown by ventriculography or encephalography. These methods are most easily carried out by the use of Lysholm's special apparatus, but the authors state that "the projections can be obtained with any flexible radiographic plant." The chapters on diseases of the skull and spine and the diagnosis of cerebral tumours by lateral and antero-posterior views cover well-known ground and add little that is new. Indeed, some of the conditions illustrated have so little bearing on neurology that they might well have been omitted, as might also the short chapter on the cerebrospinal fluid system. The chapter on cerebral arteriography is clear and succinct, but since this method is chiefly used at the present time in the diagnosis of intracranial aneurysms and angiomas it is surprising that all the illustrations in this chapter are from cases of cerebral tumour.

Lesions of the spine and spinal cord receive less space than they deserve. No doubt this ground has been so fully covered in other books on radiological diagnosis that the cursory survey given here may be adequate for its purpose. But it is surprising that no mention is made of the careful studies by Dyke and Davidoff of the separation of the pedicles at the level of intraspinal tumours. The only reference to this is that "erosion and thinning of the mesial border of one or both pedicles" may be seen in the antero-posterior view. In actual experience minor degrees of erosion are not easily seen, and are only revealed by carefully controlled measurement.

If the book as a whole is disappointing it is chiefly owing to a certain lack of balance. The problems that face the neurologist and the neurological surgeon are often cursorily dealt with, whereas there is over-elaboration of details which are more in the province of the general surgeon and physician. No doubt this will commend the book to a rather wider public, but it also detracts from its value to the radiologist who is called in to help in neurological cases.

Notes on Books

The second edition of Drs. PEARSON and HEPBURN's book on *Physiological and Clinical Chemistry* is specially suited to those medical students whose knowledge of organic chemistry is only superficial, for it is unusual among such books in providing a summary of the principles and main facts of that subject, in addition to the chapters on fats, carbohydrates, and proteins. In other respects their volume proceeds on fairly familiar and, it must be added, sound lines. Its least satisfactory feature is an arrangement which entails the complete dissociation of the principles from the practice of many analytical methods. The book is published by Henry Kimpton, and the price is 25s. net.

The Contribution of Alfred Adler to Psychological Medicine, by several authors, is No. 19 of the Individual Psychology Pamphlets (London, C. W. Daniel, 2s. 6d.). It contains a series of essays reviewing Adler's work in relation to philosophy, psychological medicine, organ inferiority, the relation of the sexes, and to general medicine, the last an admirable paper by Sir Walter Langdon-Brown. There are added a short description of Adler's conferences for teachers in Vienna and a personal appreciation of Adler himself. This is an interesting little book and gives the reader a very fair summary of Adler's work, though it is of course too slight to serve as a textbook of his methods. For that, however, the beginner can go to other sources, while the initiated will be pleasantly reminded of what he already knows.

Adventures in Respiration, by Professor Yandell Henderson, which was reviewed on October 15, at page 790, can be obtained in London from Messrs. Baillière, Tindall and Cox for 13s. 6d. net.

Preparations and Appliances

CAIDEFERRUM TABLETS

"Caideferrum" tablets (Glaxo Laboratories Ltd.) contain ferrous iron (25 mg.), a calcium salt (0.5 gramme of metal), and vitamin D (2,000 international units). The tablets are intended for prophylactic use, particularly in pregnancy to protect the mother against deficiency of iron, calcium, or vitamin D. The manufacturers emphasize the fact that the tablets are intended to prevent and not to cure these deficiencies.

EMPIRIN WITH CODEINE

Tabloid empirin (acetyl-salicylic acid) compound with codeine (Burroughs Wellcome and Co.) contains acetyl-salicylic acid, phenacetin, caffeine, and codeine. It is a combination which has, in therapeutic practice, been found effective in relieving pain, even when this is of considerable severity.

PLANTAGO FIBRE FOR CONSTIPATION

"Siblin" (Parke, Davis and Co.) is composed chiefly of highly water-absorbent fibre derived from certain species of plantago. It also contains 50 international units of vitamin B₁ in each teaspoonful. The preparation is intended for the relief of chronic constipation. It has a pleasant taste and is convenient to take. It is not absorbed or broken down in the intestinal tract, is non-irritant, and provides ample faecal bulk with optimum consistency. The vitamin B₁ facilitates improvement of intestinal muscular tone and peristaltic activity.

INTRAVENOUS STROPHANTHIN

"Kombetin" (Coates and Cooper Ltd.) is a preparation of strophanthin (Boehringer). It is supplied in 1 c.c.m. ampoules containing 0.5 mg. of the drug, and is intended for intravenous administration.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 29 1938

FOOD AND NUTRITION

The results of an inquiry into the food habits and food consumption of British people, undertaken by a firm of advertising specialists, have been brought together in a book called *The People's Food*, by Sir William Crawford and H. Broadley.¹ The inquiry dealt with 5,000 families, comprising 18,500 individuals, of all social classes—wealthy, upper middle, lower middle, skilled working, unskilled, or unemployed—in seven urban centres: London and Birmingham, where economic conditions at the time of the inquiry were good; Leeds and Glasgow, where they were less good; and Cardiff, Newcastle, and Liverpool, where economic conditions were much below the national average. It was assumed that the aggregate figures obtained from such an inquiry would be representative of the bulk of the urban families; in other words, of nearly two-thirds of the population of Great Britain. After dealing with what people eat and drink at breakfast, “elevenses,” midday lunch or dinner, tea, “high tea,” and evening dinner or supper, with the times at which these meals are taken, with the manner of cooking them, with the buying of family food supplies, and with the prevailing lack of interest displayed by housewives in dietetic subjects, the authors come to the kernel of the matter: “food expenditure and income” and “food consumption and nutritional adequacy.” The conclusion reached in regard to expenditure on food is that 17.52 per cent. of the population, or nearly 7,880,000 individuals, are living in homes where the “per caput” weekly expenditure on foodstuffs is below the minimum laid down by the British Medical Association (1933). As to the nutritional adequacy of the food consumed—arrived at by comparison with B.M.A., Stiebeling, and League of Nations standards—the conclusion is reached that between fifteen and eighteen million people consume inadequate quantities of calories, eighteen to twenty million inadequate quantities of protein, twenty-five to thirty-five million inadequate quantities of calcium, twenty to thirty-seven million inadequate quantities of phosphorus, nineteen to thirty-four million inadequate quantities of iron, thirty-seven to forty-four million inadequate

quantities of vitamin A, twenty-four to thirty-eight million inadequate quantities of vitamin B₁, and twenty-one to thirty-three million inadequate quantities of vitamin C; the lower figures being those obtained by adopting “minimum” (B.M.A.), the higher those obtained by adopting “optimum” (League of Nations) standards.

It would seem that only half the working classes achieve the League of Nations requirements in calories and protein; while practically all its members fall very considerably short in their intake of calcium, phosphorus, iron, and vitamins. The middle classes, on the whole, are adequately provided with calories, protein, phosphorus, iron, and vitamin C, according to League of Nations standards, but are probably in need of greater quantities of calcium and vitamins A and B₁. In the wealthy class there is no real shortage, except in regard to vitamin A. “In all probability between twenty and thirty millions are living on diets which are inadequate when compared with the British Medical Association ‘minimum’ standards.” Of these, eight millions have not the means to purchase foodstuffs that will provide this minimum diet, while twelve to twenty-two millions are spending weekly a sum sufficient to purchase these foodstuffs but are not expending their money wisely. “If a larger percentage of the public could be persuaded to adopt at least the British Medical Association diet, the nutritional standard of the nation, and consequently the health of a substantial proportion of the population, would be very considerably improved. If, however, they could be persuaded to base their diets on the still higher standards laid down by the League of Nations this well-being and happiness of the people of the country would be changed almost out of recognition.” How is this persuasion to be effected? Sir William Crawford and Mr. Broadley have some valuable suggestions to offer: measures of an economic character to improve the lot of the poorest classes; education, of which enlightened advertising is an important form; further research on many outstanding problems of nutrition; and the establishment of a Food Research Institute to handle the food problems of the future, on which all those interested in health, nutrition, and food are represented. And who should sponsor such a campaign? Those who will derive most benefit from the establishment of a higher standard of diet for the people: industrial concerns, food distributing trades, food manufacturers, insurance companies, and agriculture. It may be doubted, however, whether agriculture, though it would benefit greatly by the establishment of a higher national diet, is at present in a position to sponsor anything. This book again makes clear the urgent

¹ *The People's Food*. By Sir William Crawford, K.B.E., and H. Broadley. London: W. Heinemann. (12s. 6d.)

need for a national food policy based on the knowledge of nutrition which science has provided during the past thirty years.

"Just as last century the advocates of preventive medicine fought the battle for proper sanitation, so this century they will fight the battle for proper nutrition. Just as to-day sound drains and clean water are the *sine qua non* of civilized life, so will a proper diet come to be regarded as the necessity of all classes of the community. . . . A national campaign is overdue to awake the public to a full understanding of the importance of the different foodstuffs for creating and maintaining healthy bodies. A 'keep fit' campaign cannot achieve success on exercise, fresh air, and sports only, important as these are. It must have as a foundation fully developed and healthy bodies, in the production of which food is, by far, the greatest factor."

The Changing World Library has recently been enriched by the inclusion in it of a book on a cognate subject, entitled *Science and Nutrition*, by Mr. A. L. Bacharach.² It tells, from the chemist's point of view, the story of the remarkable developments in the field of experimental nutrition during the past thirty years; and tells it simply and accurately as it can only be told by one who, as Professor J. C. Drummond says in his preface, "has not only been in close touch with all the important research work of recent years, but who has himself made many valuable experimental studies." The author's main task has been to put before the reader the kind of methods used in the laboratory study of nutritional problems and the kind of knowledge obtained thereby, so that he may be in a position to apply some degree of scientific criticism to the many dietary proposals that are regularly to be found both in the lay press and in the more technical journals. This task has been successfully accomplished. After dealing effectively with the use of animal experiments and with the criticisms that are often levelled against them, Mr. Bacharach provides for those who already possess some knowledge of human nutrition a "refresher course" in classical nutritional science: a course which serves also as an outline for those not in possession of this knowledge or who have forgotten the salient facts. This summary gives a succinct account of the major food constituents—carbohydrates, fats, proteins, and certain mineral elements—the recognition of whose importance belongs to the period of "classical" nutritional theories. The author then proceeds to discuss the "trace" elements, and by an easy transition passes to the vitamins which, "though of highly complex organic structure, do their jobs in quantities of the same order as the trace elements themselves." Finally, he comes to deficiency disease, pointing out the too restricted sense in which this term is generally used, it being often confined to the

vitamin-deficiency diseases, although it must be held to include disease due to shortage of any essential constituent of food. Besides the clear-cut vitamin-deficiency diseases "it must never be forgotten," he says, "that partial vitamin deficiency, and especially partial deficiencies of more than one vitamin, are responsible for much of the general ill-defined bad health or 'mal-nutrition' " to which reference is made in earlier chapters. He stresses the need for the optimum in diet, affirming that one consisting largely of dairy produce, green vegetables, whole wheat, and meat or fish, with the additions of eggs and pulses, is pretty certain to be adequate in all essential dietary constituents, with the possible exception of vitamin D. The chemist, then, in his fragmentation of these natural foodstuffs by refined methods of chemical technique, reaches the same conclusion as those who, by their observations on man and animals, have shown that a diet composed of these natural foodstuffs in due proportion one to another contains all elements and complexes necessary for the efficiency of the function of nutrition and, therefore, for the maintenance of health so far as food is capable of supplying them; always provided that these foodstuffs are produced on soils which are not impoverished.

Mr. Bacharach lays down certain general positions which will be accepted by most of those who have worked on nutritional problems in the laboratory or in the wider field of applied dietetics, or in both. First, that the results of animal experiments are applicable, with due caution, to the problems of human nutrition and health. Secondly, that inadequate feeding in quantity and quality of food is responsible for a vast amount of ill-health and definite disease. Thirdly, that improved dietary conditions would bring incalculable improvements to the health of vast numbers of people. Fourthly, that such improvement could to some extent be brought about by educational methods. Fifthly, that a far greater improvement would result from securing that all who serve the community by working are so remunerated as to make adequate expenditure on food possible for them all. And, sixthly, that such a possibility, whether brought about by a reduction in retail prices or an increase in wage levels, or both, would, in fact, lead to that improvement in diet necessary for general improvement in health. *Science and Nutrition* is the latest addition to a series of books, which includes one entitled *Science Fights Death*, and another entitled *The Nation's Intelligence*. It shows that science fights death—and disease—by revealing the essential constituents of food, their distribution in foodstuffs, their role in nutrition, and the effects of their inadequate supply.

THE RENAL PRESSOR SUBSTANCE

Forty years ago Tigerstedt and Bergman¹ observed that saline extracts of fresh rabbit's kidney, or of the dry residue left from extracting rabbit's kidney with alcohol, produced a prolonged rise of blood pressure when injected into the veins of the anaesthetized rabbit. The active substance, which they named "renin," was obtained only from the cortex of the kidney; it was thermolabile and non-dialysable, and its pressor effect persisted after the spinal cord had been destroyed. Although this work was confirmed and extended by Bingel and Strauss² in 1908, renin attracted little further notice until two years ago. Renewed interest in it has been aroused by two converging lines of work which have focused attention on the kidney as a probable source of some chemical disturbance resulting in raised blood pressure. The first of these was the demonstration by Goldblatt and his colleagues³ that in the dog hypertension, in many features resembling essential hypertension in man, may follow constriction of the renal arteries, and the subsequent demonstration by several workers, among whom are Blalock and Levy,⁴ that this hypertension is brought about by a humoral and not a nervous mechanism. The second was the evidence provided by Prinzmetal and Wilson⁵ and by Pickering⁶ that in persistent hypertension in man excessive narrowing is still exhibited by the vessels of the hand after removal of their sympathetic vasoconstrictor tone. The suggestion therefore arises that this form of human hypertension is due to vasoconstriction of chemical rather than of nervous origin; and again the kidney may be chiefly suspected as the source of such a chemical disturbance.

The idea that certain forms of hypertension are of renal origin is as old as Bright, and it is most surprising that so little work has been done on renin, the discovery of which dates but four years after that of adrenaline. Reference to work on renal extracts during the earlier years of this century makes it clear that many workers sought it, but few were able to obtain pressor responses consistently from renal extracts. A minor reason for this failure is that saline extracts of kidney contain also depressor substances which mask the pressor effects of renin. Both Tigerstedt and Bergman and Bingel and Strauss described methods whereby most of the depressor substances may be removed; the former extracted the kidney with alcohol and, discarding the filtrate, extracted

the dry residue with saline; the latter prepared a total globulin fraction by half saturating a saline extract of kidney with ammonium sulphate. Recently Landis, Montgomery, and Sparkman⁷ have described a third method, in which heating saline extracts of kidney to 56° C. for twenty minutes precipitates depressor material along with most of the protein, the resultant filtrate giving a pure pressor response in the unanaesthetized rabbit. A more important reason for the failure of earlier workers to detect renin is that the pressor action of renin is reduced or abolished by anaesthetics, as Pickering and Prinzmetal⁸ have recently shown; for, of course, it has been, and still is, customary to test extracts for their vasomotor properties on the anaesthetized animal. There is now no doubt that renin is a normal constituent of the renal cortex of most species, and apparently confined to this. Its properties resemble those of a protein: thus it is destroyed by heating for two hours at 60° C., by strong acids and alkalis, and by alcohol at a temperature above 0° C. but not by alcohol at -10° C.; it is non-dialysable and appears chiefly in the pseudoglobulin protein fraction.⁹

As has been mentioned, there is a strong presumptive case for supposing that renin may be the agent responsible for certain forms of human and experimental hypertension. Landis, Montgomery, and Sparkman have shown that in one respect renin is the only chemical substance known whose behaviour is compatible with that of the agent in persistent hypertension in man. Thus in human hypertension the peripheral blood flow appears to be normal, and renin is the only known pressor substance which will raise the blood pressure in the unanaesthetized rabbit without simultaneously reducing the blood flow through its ears. More direct evidence is, however, needed, and several attempts have been made to detect increased quantities of renin in the kidneys of dogs with hypertension due to renal ischaemia, positive results being claimed by Harrison and his colleagues⁹ and by Prinzmetal and Friedman.¹⁰ A solution of this question demands some method for the assay of renin, and the great difficulty has been that the anaesthetized animal responds inconsistently to the substance. Pickering and Prinzmetal have, however, demonstrated that in the unanaesthetized rabbit the response to a given dose of renin is constant provided that sufficient time is allowed between injections for the blood pressure to return to its resting level. They have also found that the renin content of the dry residue left after extracting

rabbit's kidney with alcohol remains unchanged for many months if the preparation is kept cold. Using this preparation as a standard, and finding the doses of standard and unknown solutions which will give similar rises of blood pressure in an anaesthetized rabbit, the renin content of the unknown solution may be assayed in terms of the standard. With this or some other similar method it should be possible ultimately to decide whether the renin content of the kidney is or is not altered in hypertension.

Finally, it may be said that although renin is at present most fancied as the agent responsible for hypertension the problem still remains open. There can, nevertheless, be no question that it is an interesting and hitherto much-neglected substance which must have some place in the economy of the body. What this place is cannot at present be stated, but more will certainly be heard of renin in the years to come.

COMPARATIVE STUDY OF CANCER OF THE ALIMENTARY TRACT

The study of cancer of the alimentary tract in animals and in different races and classes of mankind has revealed contrasts of great interest. Ruddock and Willis¹ describe a carcinoma of the stomach in a dog with the comment that the stomach is one of the rarest sites of cancer in dogs. Gastric cancer is equally, or almost as, rare in other animals. The significance of this contrast with clinical experience is discussed by Wells, Slye, and Holmes.² Their personal observations were made on 142,000 mice of Miss Slye's stock all dying from natural causes and mostly of cancer age. Although, according to earlier reports, there were more than 100,000 cancers in this series, there were no tumours of the oesophagus, only fifteen primary malignant tumours of the stomach, and only nineteen of the intestines; in eleven instances the intestinal tumour originated in a prolapsed rectum. Wells, Slye, and Holmes conclude that the lower animals escape the carcinogenic stimuli which assail the human alimentary tract. This inference needs close scrutiny. The frequency of cancer in the prolapsed rectum supports the essential assumption that the alimentary tract of mice is capable of developing cancer under suitable conditions, but the assertion that cancer can be easily produced experimentally in the stomachs of rodents will not pass unchallenged. Waterman produced squamous carcinomata in the fore-stomachs of mice by administering a carcinogenic substance; other investigators failed to produce tumours of any kind, and confidence in Fibiger's classical experiments on the production of gastric cancer by a parasite has been shaken by the observations of Passey and of Cramer. According to present views, cancer similar to gastric cancer in man might be produced in animals which rarely develop it

spontaneously by applying a stimulus of suitable kind and intensity; but this has not yet been done. Success may depend on finding the appropriate stimulus. Susceptibility to the known carcinogenic agents varies greatly in different species of animals and in different tissues, and it is not certain that the stimuli which produce gastric cancer in man would be effective in mice. In contrasting gastric cancer in man and animals it is important to recognize that the incidence of human gastric cancer is not uniformly high. The greater incidence in the poor as compared with the rich was discussed by Sir Arthur Hurst in his Harveian Oration last year.³ A promising field of investigation has also been opened in the Dutch East Indies. The incidence of gastric ulcer and of gastric cancer in the native Javanese is extremely low, while the incidence of both conditions in the Chinese resident in Java is similar to that in Western countries. Bonne and his colleagues⁴ are investigating the possible causes of this difference. They avoid the seemingly endless dispute as to how often cancer supervenes on ulcer, but believe that ulcer and cancer must have at least one common aetiological factor. Gastritis, in general, and erosions were about equally common in Javanese and Chinese stomachs; it seemed, therefore, that some factor which in Chinese and Europeans converts an erosion into an ulcer was absent from the Javanese. Chronic atrophic gastritis and goblet-cell metaplasia were common in the Chinese; but more material is needed to show whether these are precancerous conditions. A comparison of the habits and diets of the two races is in progress, though the difficulties in the interpretation of observations of this kind are not minimized. These comparative studies may well yield results of great practical importance.

LUNG PHYSIOLOGY AND COLLAPSE THERAPY

The methods so far available for testing the functional capacity of the lungs are either not reliable enough or are too complicated for general use. The difficulties are due largely to two facts: the function of the lung depends on two related but distinct components—the volume of the respiratory exchange and the gaseous blood changes—and certain tests require exertion or movement which it may be impossible or inadvisable for some patients to undergo. An important advance has been made in the method of bronchspirometry, introduced by the late Professor Jacobaeus, which allows the function of each lung to be investigated separately. It calls for expert bronchoscopy and spirometric experience. We drew attention to the matter some time ago,⁵ and a recent account⁶ makes it clear that bronchspirometry offers much hope for the future of thoracic surgery. Kaltreider, Fray, and Philips⁷ have carried out a detailed investigation in twenty cases of pulmonary tuberculosis treated by thoracoplasty. Measurements were made from seven months to ten years after opera-

tion. In only two patients were the observations made both before and after the operation. The total pulmonary capacity and its subdivisions were determined, radiographic measurements were taken, and the oxygen saturation of the arterial blood and the morphology of the red blood corpuscles investigated. In order to study the effect of compression of the lungs on the right heart the venous pressure and velocity of the flow of blood were measured. The normal values for the capacity of the lungs (before operation) were predicted from the standing body weight. Thoracoplasty lowered the total and vital capacities; this reduction was roughly proportional to the number of ribs resected, and was greater when the phrenic nerve had also been paralysed. Thoracoplasty also diminished the ability of the patient to expand the chest. An anoxic anoxia in these patients was not associated with polycythaemia, and the morphology of the red corpuscles was normal. The venous pressure was slightly elevated, being higher on the operated side, and the blood velocity was slightly delayed. At rest and during moderate physical exertion patients with thoracoplasty had a rapid and shallow type of breathing compared with normal persons. A correlation was found between their degree of disability and the lowering of the vital capacity and pulmonary reserve. Harter, Overholt, and Perkin¹ determined the lung volume in seventy-two consecutive patients, and in thirty-two of them after thoracoplasty. Lambert, Berry, Cournand, and Richards² carried out a detailed study of the pulmonary and circulatory function of the lungs both before and after thoracoplasty in eleven patients, and conclude that the level of vital capacity is not a good criterion either of functional capacity (dyspnoea) or of operative risk; a more satisfactory index of dyspnoea is the ratio of actual to maximum ventilation. The problems raised in the above papers make it plain that further research is needed to establish collapse treatment of pulmonary tuberculosis on a more rational basis.

SKIN REACTIONS IN TOXAEMIA OF PREGNANCY

It was Zweifel who, in a moment of depression, called eclampsia "this disease of theories," a description which in view of the number and variety of the opinions on its aetiology remains more than justified. The field is, however, somewhat narrowed by the general acceptance of the basis of a circulating toxin, for though such a substance has never been specifically isolated its existence seems certain from the pathological changes found post mortem in the liver, kidneys, and reticulo-endothelial system, all of which excrete toxin. The clinical evidence is also confirmatory—the increase with advancing pregnancy, the reaction to eliminative treatment, the association with placental degeneration, etc. Attempts to identify the toxin biochemically have been unsuccessful, but its essentially allergic nature has recently been demonstrated by Belikoff and Manevitch.³

It appears from their experiments that the serum of eclamptic patients produces a definite local reaction when injected subcutaneously into patients suffering from toxæmia of pregnancy. The reaction is specific for these cases, and is negative in non-pregnant or pregnant non-toxaemic patients. It is thus not only valuable confirmatory evidence of toxæmia, but by appearing actually before the onset of the ordinary clinical signs it allows of earlier diagnosis and prophylaxis of the disease. The technique is to inject subcutaneously into the arm 2 c.cm. of a 10 per cent. solution of the serum in physiological saline; a strongly positive reaction produces an immediate erythema and vesiculation, lesser degrees of toxæmia causing a slight delay. Apart from the diagnostic importance of this work, it is possible that such serum might be used with advantage as a desensitizing agent in known cases of pre-eclamptic toxæmia. Such a property is suggested by the extreme rarity with which eclampsia recurs in the same person (3 per cent. according to Bumm), and though clinical experiment must be delayed until further biochemical assay and standardization provide a reasonable margin of safety, it is possible that this new approach may aid materially in the reduction of the disease.

THE VIRUS OF LYMPHOGRANULOMA INGUINALE

Eight years ago the causal agent of lymphogranuloma inguinale was shown by Helleström and Wassen¹ to be filterable, and was added to the rapidly growing group of viruses. Even before this, small granules had been described in the cells from inguinal buboes by Gay Prieto (1927), and similar granules were observed and figured by Findlay (1933), who expressed the view that these minute bodies were probably the virus. It was, however, the researches of Miyagawa and his colleagues some two or three years later which constituted the first detailed study of these minute bodies, and it is generally accepted to-day that they are, in fact, the virus. They are very small coccus-like particles measuring as a rule 0.125 μ to 0.175 μ , and they have been observed in virulent material of various provenance. Recently a note appeared by G. M. Findlay, R. D. Mackenzie, and F. O. MacCallum,² announcing that they had observed forms of this virus which resembled those described in psittacosis by Bedson and Bland³ in 1932. It is interesting to note that the large form of lymphogranuloma inguinale virus seen by these workers occurred particularly in the early lesions, and that it often showed an appearance suggesting division by fission. Forms intermediate in size were observed; in fact, the different forms and their sequential relationship suggest that this virus passes through the same cycle of development forms as psittacosis. The only other virus in which a similar phenomenon has been observed is that of inclusion conjunctivitis,⁴ although the inclusions seen in trachoma suggest that here also

⁴ *Amer. J. Ophthalm.*, 1934, 17, 1019.

the same thing occurs; and it may not be without significance that these viruses stain readily by Castaneda's method, whereas what one might term "typical" viruses like vaccinia, fowl-pox, herpes, and chicken-pox are not stained by this procedure. The staining method of Castaneda was devised by him for Rickettsia, and some of the appearances presented by Castaneda-positive viruses resemble what is found in the case of Rickettsia. It has in fact been suggested on more than one occasion that these particular viruses are Rickettsia. Lillie⁵ has named the virus of psittacosis *Rickettsia psittaci*. Cuénod and Nataf⁶ have stated that in their opinion the virus of trachoma is a Rickettsia, as is also, according to the view recently expressed by M. J. Caminopetros,⁷ the virus of lymphogranuloma inguinale. It may well be that with increasing knowledge it will be found that the Castaneda-positive viruses and the Rickettsia should be grouped together and separated from the other viruses. At the moment, however, this indiscriminate use of the term Rickettsia is to be deplored. Rickettsia as a generic name is excusable on historical grounds, but it has no true biological sanction. Further, the one positive character possessed by the Rickettsia, apart from their morphology, which admittedly is definitely microbial, is that they all have an arthropod host. Cuénod and Nataf have claimed that the virus of trachoma is infective for lice, but the viruses of psittacosis, lymphogranuloma inguinale, and incidentally the agents described by Coles in South Africa in conjunctivitis of cattle, sheep, and goats, have not been shown to have an insect host; so with the possible exception of trachoma virus there is not even this excuse for calling them Rickettsia.

CARE OF LUNATICS IN NIGERIA

In a recent report⁸ Dr. R. Cunyngham Brown deals with lunacy in Nigeria, the largest and most populous of the four British West African Colonies. After an extensive tour of the Northern and Southern Provinces he estimates that the proportion of mentally deranged people is not less than 2 per 1,000 of the population, and that there are probably some 40,000 persons in Nigeria who are either imbecile, epileptic, or insane. The vast majority of these people remain in their villages, where, on the whole, they are kindly and even solicitously treated, though they naturally suffer from the lack of medical attention and advice. Of this large total of 40,000 only 290 figure in the official returns of 1935 as lunatics or suspected lunatics, including 121 actually certified. An interesting point noted by Dr. Cunyngham Brown is that the incidence of lunacy appears to be just as large among the primitive peoples as among those Africans who have been brought into contact with Western civilization. Institutions for certified lunatics are stated

to be far behind the times, while custodial detention is emphasized at the expense of remedial treatment. He stresses the desirability of the establishment of more asylums, and, in view of the fact that lunacy in Nigeria appears to be increasing, he advocates the provision of ample acreage to permit of further extensions. With regard to lunatics who remain in their villages, the building up of an organization to provide a measure of supervision and medical guidance is suggested. Dr. Cunyngham Brown also recommends the appointment to the medical services staff of a specialist officer thoroughly conversant with this branch of medicine.

A NEW ANTI-MALARIAL DRUG

A new compound, "certuna," a dialkylamino-oxyquinolylaminobutane, has recently been reported by Kikuth¹ as having strong gametocidal action comparable to that of plasmoquine. The malarial parasite has such a complex developmental cycle that it is not entirely surprising that anti-malarial drugs do not have a consistent action on all stages of the parasite. Quinine and atebrin exert a powerful effect upon the asexual forms found in man and dramatically control the clinical manifestations of malaria, but plasmoquine is practically useless for this purpose. Plasmoquine, however, appears to have a devitalizing effect on the infection in that it lessens the frequency of relapse and it also has a specially selective action on gametocytes; its use is not without interest, therefore, both to the clinician and to the hygienist. Unfortunately it sometimes gives rise to toxic manifestations even in moderate dosage, and it is on account of this toxicity that its value as a prophylactic, since it is also lethal to sporozoites, is in practice nullified. Clinical trials of the new compound "certuna" by Sioli² and others suggest that the new drug is much better tolerated by man than is plasmoquine, and further observations, particularly with regard to its influence on relapses, or its use as a prophylactic, will be awaited with interest.

In view of the widespread disquiet among members of the medical profession as to the incompleteness of the plans for the organization of medical services and their lack of co-ordination, the Central Emergency Committee of the British Medical Association has asked the Minister for the Co-ordination of Defence to receive a deputation. Sir Thomas Inskip has agreed to receive this deputation on November 8.

The British Postgraduate Medical School announces that the Kettle Memorial Lecture will be delivered at the London School of Hygiene and Tropical Medicine, Keppel Street, W., on Thursday, November 24, at 5 p.m. The lecturer is Professor W. W. C. Topley, F.R.S., and he will speak on "The Place of Pathology among the Medical Sciences."

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

SULPHONAMIDE CHEMOTHERAPY IN SURGICAL INFECTIONS—II

BY

A. J. COKKINIS, M.B., B.S., F.R.C.S.

Gonococcal Infection

The gonococcus has always been a difficult organism to eradicate, and although it can be got rid of by sulphonamide therapy in a small fraction of the time taken by other treatments, this is by no means easy. Nevertheless, in a series of more than 600 cases, Dr. McElligott and I have shown that a male patient with gonorrhoea (whether simple or complicated) treated with sulphanilamide can be given a 90 per cent. chance of complete cure in a few weeks if the following principles are faithfully observed: (a) Chemotherapy must not be started until the discharge is at least eight to ten days old (it takes that much time for immunity to develop). (b) It should be preceded and combined with vaccine treatment (with the object of increasing this immunity). (c) It should be continued for three weeks, and the dosage must be adequate (for example, 4 grammes of sulphanilamide daily for an adult male of 11 or 12 stone). (d) Administration must be properly spaced (preferably four doses each day) and absolutely uninterrupted. (e) Relapses should be treated with a second course after an interval of some weeks. (f) The most rigorous tests and three months' observation must be passed before a patient is pronounced cured. Treatment with small doses (such as one tablet three times a day) over short periods is worse than useless; this and other errors of technique may lead to obstinate resistance to subsequent chemotherapy. Owing to the large total dosage required special care must be observed against the more serious toxic properties of the drugs. Minor toxic effects are naturally very common with this dosage, and may constitute an obstacle to effective administration, particularly in female patients.

The above summary applies to sulphanilamide only. In its place we are now using T 693, which promises to produce at least equally good results, but unfortunately without any diminution of the incidence of toxic effects. The only other sulphonamide with a definite action on gonococcal infections is uleron, which we have tried in some 150 cases. The immediate results are often excellent; but whatever method of administration is employed most cases relapse, and continue to do so until a more powerful sulphonamide compound is used.

Coliform Infections

Sulphonamide chemotherapy produces its best results in cases of "primary" urinary infections with *B. coli* and certain other organisms of the coliform group. These are cases of pyelitis, cystitis, or genital infections without an obvious gross cause (for example, a senile prostatic enlargement). Quite small doses and a short period (such as 2 grammes of sulphanilamide daily for six to eight days) suffice to clear up, both clinically and bacteriologically, most cases of "primary" pyelitis or pyelitis of pregnancy. I have noted, however, a tendency to relapse, and in consequence it is now my practice in non-urgent cases to give an autogenous vaccine (three or four times

weekly) for one to four weeks before starting sulphonamide treatment, and to increase the period of chemotherapy to ten to fourteen days; also to give further courses if the pyuria recurs.

Cases of "secondary" urinary infection (such as those complicating an enlarged prostate or a calculus) are much more difficult to cure permanently, but a "cure" is less important than in the former group. The principal treatment here must be directed to the primary cause, whatever this may be, and the chief object of the chemotherapy is a temporary clearing up of the urinary infection as an adjunct to operation. This is most effectively obtained with sulphanilamide or T 693, but patients with this type of urinary infection may be too debilitated to tolerate these toxic drugs easily, and I have often preferred the less complete urinary disinfection obtained with a short four-day or five-day course of uleron (3 grammes daily) or prontosil soluble (10 to 20 c.cm. of 5 per cent. daily). This course should be given during the pre-operative stage of a prostate case, and may be repeated after prostatectomy to deal with the common post-operative exacerbation of the urinary sepsis.

Acute Appendicitis

The repeated discovery of coliform bacilli and non-haemolytic streptococci in acute appendices and in the peritoneal exudate induced me to explore the possibilities of sulphonamide chemotherapy in this disease, and there is now no doubt in my own mind that an indiscriminate use of these compounds in acute appendicitis—and in other urgent abdominal conditions—can be dangerous. An experience of more than forty cases treated in the past nine months, many of them bacteriologically controlled, has led to the following conclusions: (a) Sulphonamide therapy should not be used in the first forty-eight hours of an acute attack of appendicitis, either as an alternative to operation or as an adjunct to it. The only rational treatment for such cases is, and I think always will be, removal of the appendix. Chemotherapy at this stage is definitely unwise, as it may mask a dangerous complication or perhaps interfere with the first stages of the immunity response. (b) On the other hand, I have found sulphonamide compounds to be of real value as an adjunct to operation in the more advanced stage, when the appendix is perforated or necrosed, there is a purulent effusion in the peritoneal cavity, and the immunity response is presumably awakened. In such cases post-operative chemotherapy often rapidly clears up the peritoneal infection, and thus may prevent a prolonged illness, with wound sepsis and more dangerous complications. (c) The most striking results, however, have been obtained in late acute appendicitis with localized lump formation (plastic peritonitis without obvious abscess development). For some years it has been customary to treat these cases by expectant methods, which aim at complete resolution of the inflammatory process before appendicectomy is performed. Unfortunately, this expectant treatment may take several weeks before its object is attained, and sometimes it fails to prevent the development of an abscess, ileus, or other complications. This is the type of case in which sulphonamide chemotherapy seems most successful. Not only does the lump completely resolve and the patient become well often in a few days (without starvation), but abscess

formation and other complications are obviated, and appendectomy may be safely performed after only a small fraction of the time one had to wait in pre-sulphonamide days.

The compounds mostly used in such cases have been prontosil soluble (10 to 30 c.cm. of 5 per cent. solution daily) and sulphanilamide (2 to 4 grammes daily). The former is particularly suitable for the first few days after an operation, when sulphanilamide often causes very troublesome toxic effects, such as vomiting, prostration, and cyanosis. Best results have been obtained when the chemotherapy is continued for about ten days.

Appendix and Other Abdominal Abscesses

Cases of definite appendix abscess have responded to sulphanilamide at least as well as those with a lump but without evidence of suppuration. Of eight such abscesses treated, every one resolved completely in five to fourteen days, while constitutional symptoms cleared up in twenty-four to seventy-two hours. None had to be drained, and only one developed a relapse (after two months), which was treated by early appendectomy. The dosage of sulphanilamide has been between 2 and 4 grammes daily, and the period of administration has varied between six and fifteen days.

I have also obtained complete resolution of a large and increasing subphrenic abscess (of appendicular origin) in a desperately ill patient, with ten days' sulphanilamide treatment. The clinical improvement was immediate, while the rapid diminution of the abscess was easily followed by radiography.

Acute Cholecystitis and Cholangitis

The usual causative organisms are again coliform bacilli and streptococci, and the lesions might therefore be expected to respond to chemotherapy. A trial of sulphonamide compounds in six cases of acute cholecystitis and two of acute cholangitis has indeed shown that recovery from the acute illness is very materially hastened by the chemotherapy (Fig. 1). Unfortunately, four of the cholecystitis cases, all with gall-stones, afterwards relapsed and were treated by cholecystectomy. One may conclude that in such cases the chemotherapy is likely to be of only secondary or palliative value.

Acute General Peritonitis

My experience with sulphonamide compounds in acute peritonitis suggests that, when used correctly, chemotherapy may prove of life-saving value, but also that when used indiscriminately it may prove the reverse. The deciding factor again appears to be the immunity response of the patient. Although the cases treated have been comparatively few, they show quite decisively that sulphonamide compounds should not be used as a prophylactic measure against peritonitis in such lesions as perforated ulcer and intestinal strangulation, or after such operations as colectomy. They also suggest that it is unsafe to employ chemotherapy in the very early stage of actual peritonitis—that is, while the effusion is still serous and the immunity presumably unawakened. On the other hand, when the more powerful sulphonamide compounds have been administered to cases of fully developed coliform or streptococcal peritonitis, with either a profuse purulent effusion or an extensive peritoneal oedema, the result has usually been a dramatic and lasting improvement (Fig. 2). Once started, the chemotherapy should be continued in adequate dosage for at least ten days, but it should never be begun until after any removable and unlocalized source of infection has been dealt with by operation.

Infections of the Hand

No condition gives more striking evidence of the bacterial selectivity of sulphonamide compounds. In a fairly large number of septic hands treated no case of pure staphylococcal whitlow has responded. On the other hand, infections from which streptococci had been isolated on the whole responded very well. It is therefore necessary to make a bacterial diagnosis—for example, by aspiration—before chemotherapy is commenced. Streptococcal infections tend to spread along the superficial and deep

FIG. 1.—Temperature chart of case of acute cholangitis, treated with sulphanilamide and prontosil soluble.

FIG. 2.—Temperature chart of case of streptococcal peritonitis treated with sulphanilamide.

lymphatics, and nearly all the successful cases have been infections of the great spaces of the hand or examples of acute lymphangitis. Tendon sheath infections are mostly staphylococcal, and of six such cases treated with sulphanilamide the only one which showed any improvement was a mixed infection of staphylococci, streptococci, and, strangely enough, *Cl. welchii*. The staphylococcal cases proved equally resistant to ulcers.

Owing to the speed with which streptococcal infections of the hand spread, it is unwise in these cases to wait for immunity, and chemotherapy should be started as soon

as bacterial diagnosis is made. Whenever possible, however, this should be combined with some form of rapid immunotherapy, such as by anti-streptococcal serum. The dosage of sulphanilamide used has been 2 to 4 grammes daily for five to twelve days. In no case should the chemotherapy be employed as an alternative to surgical drainage if there is the least indication for the latter. The only exceptions to this rule are cases of streptococcal lymphangitis, where the primary focus of infection is often insignificant (for example, a puncture of the finger at a septic operation) and where the real danger is a septicaemia. I have seen two such cases, both caused by a haemolytic streptococcus and both already with evidence of blood infection, respond with dramatic suddenness to sulphanilamide. This experience justifies the hope that the new chemotherapy may afford some protection against a danger to which our work exposes us, and by which many a brilliant career has in the past been brought to an abrupt end.

Infections of the Skin and Subcutaneous Tissues

Here again the results of chemotherapy depend entirely on the nature of the infecting organism. Thus, in several cases of carbuncle (staphylococcal) treated with sulphanilamide or uleron there has been no response. On the other hand, very marked improvement has been observed in cases of streptococcal cellulitis, and, of course, in erysipelas.

Infection of Bones and Joints

Osteomyelitis is predominantly a staphylococcal disease, and, as might be expected, sulphonamide chemotherapy produces little or no results in it. Actually, some slight benefit was noted in three cases, one of acute and two of chronic osteomyelitis, but it proved very transient.

Infective Arthritis, on the other hand, is often caused by sulphonamide-susceptible bacteria, and I have obtained striking results with sulphanilamide in both gonococcal and streptococcal cases. Now, with the introduction of T 693, one may reasonably expect to be able to influence pneumococcal arthritis also.

Toxic Arthritis (for example, rheumatoid) belongs to a very different category, and is a condition in which useful research could be done in general practice. I know of several cases treated with repeated courses of sulphanilamide, preceded by and combined with vaccine, in which improvement has been obtained. If possible, autogenous vaccine should be used, but a stock anti-rheumatic vaccine may be employed when there is no obvious focus of infection. Improvement is most likely in the relatively acute cases of rheumatoid arthritis seen mostly in youngish people, and I recommend small doses of sulphanilamide (1.5 to 3 grammes daily) in three or more 14 to 21-day courses, with three to four weeks' intervals, a full course of vaccine being given as well.

Traumatic Surgery

In this branch of surgery my experience with sulphonamide chemotherapy has been rather disappointing. For some time it was hoped that it might be of service in the prevention of wound sepsis (for example, in traffic accidents), but I am now very doubtful if such prophylactic use is of any value. On the contrary, there is reason to believe that it may do harm. It is quite rational, however, to treat an infected compound injury with sulphonamide, if the infection is already established, and provided at least one of the organisms present is known to be susceptible. Striking improvement has been seen in several such cases, particularly when the suppuration has been mostly in the

superficial tissues, and also in one case of clinical gangrene, in which the diagnosis was unfortunately not confirmed bacteriologically.

Conclusion

The more one learns of the new chemotherapy the more one feels that it should be employed only when an infection has become fully established, and, as a general rule, the longer the infection has been in existence the better the results are likely to be. Occasional exceptions are bound to occur, such as when a fulminating infection threatens to overwhelm the patient, and when an attempt to arrest bacterial growth must be made without waiting for the immunity response, which may or may not develop. There is one application of sulphonamide chemotherapy, however, which in my experience has proved quite valueless (and even dangerous), and that is its preventive use against the threat of an impending infection.

PROPHYLAXIS OF THE COMMON COLD

BY

J. B. SHERMAN, M.B., B.S.

Medical Officer, Bournville Works

There are few, if any, medical conditions which cause such severe economic losses to employer and employee as the common cold. The great number of so-called treatments and prophylactics bears testimony to our failure to cope with the problem. One of the difficulties facing the general practitioner is that of being able to treat under strict control large numbers of patients, this being the best method of estimating the value of any form of treatment. In the present state of our knowledge it would seem that methods of prophylaxis offer more hope of success than those of treatment.

In view of the opportunity afforded at these works it was decided to try the effects of some of the better-known prophylactics upon a rather larger scale than usual, and by keeping strict records to obtain some idea as to their comparative values.

The Methods Used

Four methods were chosen as all holding out reasonable prospects of success.

1. *Ultra-violet Irradiation*.—The good effects of this as a preventive of respiratory infections have often been quoted. The apparatus used here was a pair of Watson carbon arc lamps. Exposures were given at a distance of three feet twice a week, working up to a total exposure of fourteen minutes. This was carried on throughout the winter months. No ill effects were noticed.

2. *Vitamins A and D*.—Vitamin A, 6,000 units, and vitamin D, 1,000 units, were given in the form of one capsule (adexolin) a day after a meal. A course lasted throughout the winter. A certain number of patients suffered from nausea and other gastric discomfort, but otherwise no ill effects were noticed.

3. *Dissolved Vaccine*.—As supplied by Glaxo Laboratories this consists of a mixed vaccine of organisms found in the upper respiratory passages. The cell walls of the organisms are dissolved by sodium lauryl sulphate. Four injections were given subcutaneously at five-day intervals, starting with $\frac{1}{2}$ c.cm. and increasing to 1 c.cm. for the three subsequent doses. The immunity conferred was intended to last the whole winter. In patients who already had colds it was found to make them worse. The injections often caused stiffness and pain in the arm, but in only one case was real disability noted.

4. *Entoral Vaccine*.—These were mixed vaccines in a dried form in capsules for oral administration. They were given on an empty stomach—one a day for the first week and then one a week for the whole winter. Apart from causing discomfort to patients who already had colds and causing nausea in others, no other ill effects were noticed. In numbers of patients treated by methods 3 and 4 there seemed to be an increased susceptibility to colds.

5. *Control Group*.—This consisted of 593 patients who received no prophylactic treatment but of course were free to treat any colds they had by ordinary means. Records were kept of all patients and controls by personal cards filled up week by week and collected monthly, so that as far as possible the information was accurate.

Results

The results were tabulated to give an idea of the value of prophylaxis as a whole and of the comparative values of the various methods. Altogether 1,928 patients were observed, of whom 1,655 completed the course. Of this number 593 were controls, so that full results of treatment were obtained of 1,062 patients.

There were two possible effects to be expected from treatment—either a reduction in the number of colds contracted, or a reduction in the severity of colds. Either or both results would affect the loss in working days per employee. As the treatments were purely voluntary it was expected that those who had suffered mostly in previous years would form the majority of those seeking treatment, and this would make results seem less good than otherwise.

It was found, however, from our records that the number of working days lost through colds per employee for the winter of 1936-7 was 2.12 for the control group and 2.24 for the group receiving treatment. It was not, therefore, considered necessary to make any correction for this factor.

1. *Number of Colds*.—As seen in the table the only treatment to produce any reduction in the number of colds per person was ultra-violet irradiation, and this shows a substantial decrease.

2. *Severity of Colds*.—There has been no reduction in the average duration of colds. The number of working days lost per cold does, however, show a definite decrease as a result of all treatments except entoral vaccine. There would therefore appear to be a lessening of severity of colds, if one accepts days lost as an index of severity, and this seems reasonable. Taking the results as a whole, the number of working days lost per person has been substantially reduced by ultra-violet irradiation and slightly reduced by the vitamin treatment.

Comments

It is usually accepted that the good effects of ultra-violet irradiation are due to the formation of vitamin D in the skin. It is of interest to note the distinctly better results from the irradiation as compared with those from the oral administration of vitamin D. The question arises as to whether ultra-violet light acts also in some other way or whether vitamin D given orally is less effective than when formed naturally in the skin.

While the figures given for treatment by dissolved vaccine are not startling, it was found that a large percentage of patients so treated obtained complete relief from colds, although they had suffered during previous winters. Several reports were received of mild chronic catarrhal conditions completely clearing up. Five patients who complained of mild joint pains volunteered their delight at the disappearance of these. The two latter facts may prove of value in some cases from the point of view of treatment.

It was decided, in the case of entoral vaccine treatment, to give only one capsule a week on the score of expense.

Our results with this method might have proved better had we given bigger doses, although a large number appeared to be worse on the given dose. If prophylactic treatment is to be offered to some thousands of employees, as we hope to do, then expense is a definite factor with which to reckon. One might stress the difficulty of making patients take regular daily or weekly treatment over some months.

Summary

An attempt has been made by a large industrial concern to estimate the value of some current methods of cold prophylaxis: 1,655 employees were observed, including controls.

It was found that the only method of real value was ultra-violet irradiation, which reduced both the severity and the number of colds in patients so treated. The method is cheap and easily applicable to large numbers of employees. Its use by big industrial concerns would definitely lower the tremendous economic losses at present caused by the common cold.

Table showing Results of Treatment for Colds (December, 1937, to March, 1938) (Males and Females)

Type of Treatment given	No. of Persons	No. of Colds	No. of Colds per Person	Average Duration of Cold (Days)	Working Days lost per Cold	Working Days lost per Person	
						1938	1937
Controls ..	593	875	1.48	6.65	0.72	1.06	2.12
All treatments ..	1,062	1,646	1.55	7.09	0.65	1.01	2.24*
Entoral ..	283	427	1.51	6.87	0.79	1.19	
Adexolin ..	330	569	1.72	7.09	0.59	1.01	
Dissolved vaccine ..	213	402	1.89	7.53	0.61	1.15	
Ultra-violet ray ..	236	248	1.05	6.76	0.63	0.67	

* Not treated in 1936-7.

I wish to express my gratitude to Messrs. Cadbury Bros. Ltd., whose generosity made this investigation possible, and to Miss Tattersall and Miss Maton for valuable assistance with the records and statistics.

FORLANINI INSTITUTE: SCHOLARSHIP

The Privy Council announces that in connexion with the Carlo Forlanini Health Institute of Rome, a clinic for diseases of the respiratory system and tuberculosis, which organizes annually (from January to April) courses of training in phthisiology for foreign medical practitioners, the National Fascist Institute for Social Welfare offers to British medical practitioners:

1. A scholarship consisting of exemption from fees for registration and attendance at the course, free board and lodging at the Institute, and other facilities, including special railway facilities.

2. Three nominations entitling the holders to exemption from fees for registration and attendance at the training course, and other facilities, including special railway facilities.

Candidates must be qualified medical practitioners of at least three years' standing who have rendered effective service in specialized medical clinics or sanatoria or other scientific institutions for the treatment of tuberculosis. Any publications and attendance at other courses specializing in phthisiology can be considered as claims for preference.

With the concurrence of the Privy Council the British Medical Association has undertaken to receive applications from medical practitioners, who should communicate with the Secretary of the Association at B.M.A. House, Tavistock Square, London, W.C.1, not later than November 1, 1938 giving details of age, qualifications, and experience.

OPENING OF THE NEW SESSION

WELSH NATIONAL SCHOOL OF MEDICINE

GENERAL MACARTHUR ON THE WISDOM OF THE OLD LEARNING

The opening sessional address at the Welsh National School of Medicine, Cardiff, was given on October 7 by Lieutenant-General W. P. MACARTHUR, Director-General, Army Medical Services, the text of whose remarks was Chaucer's line:

"And out of oldē bokes, in good feith,
Cometh al this newē science that men lere."

His object, he said, was twofold: first to try to show how much could be learned in medicine by simple observation, and also that, as Horace expressed it, there were heroes who lived before Agamemnon. Owing to his heavily increased duties in the international crisis he had taken much of his material from previously published papers of his:

General MacArthur began by glancing at the medicine of the early Christian era. In Europe the advance of medicine along scientific lines came to an end with the eclipse of Greek medical learning about A.D. 200, but the light, though much dimmed, continued to burn in the Moslem Empire, with its capital at Bagdad, where they possessed Arabic translations of the ancient Greek experimentalists and added to the sum of knowledge by observations of their own. Rhazes (born A.D. 860) differentiated measles from small-pox, and part of his description was judged by Osler good enough for inclusion in his textbook.

Early Observations on Typhus Fever

After describing with many vivid touches the reaction in Western Europe to the universal epidemic of plague, called to-day the Black Death, General MacArthur discussed another disease which our ancestors had every opportunity of studying—namely, typhus fever, otherwise spotted fever, famine fever, jail fever, camp fever, and, most ominously, hospital fever (the name "typhus" was given to it only in the middle of the eighteenth century). The terrible epidemic transmitted by the louse scourged these islands for centuries, always smouldering somewhere, and ready to flame up in times of war and famine.

On reading old accounts of typhus fever one could not but be struck by the wide clinical knowledge of the disease shown. These old observers knew that the rash might appear on the fourth day or not until the fourteenth, or might not be seen until after death: they were aware that some cases of typhus have no rash at all. It was pointed out a few years ago that in cases of typhus without an eruption a ligature tied around the arm might dilate the damaged vessel sufficiently to produce petechiae distal to the ligature, but this effect of a ligature was known centuries ago. Boghurst, writing of the London plague in 1665, gave a careful differential diagnosis of typhus and plague with tokens. These old writers recognized, further, an atypical variety of typhus fever like Brill's disease, very difficult to diagnose because of its mildness; and they observed that when such cases were crowded together the disease, through what they called the concentration of contagion, assumed its malignant petechial character and grew very mortal. The complications were clearly set out: the deafness; the eye lesions, including the late cataracts; suppurations of the parotid and submaxillary glands; orchitis; adenitis; late oedema; gangrene of the skin, of the extremities, of the intestine; even the rare patches of softening in the brain followed by paralyses, and the rare orbital abscesses. Indeed, the speaker

doubted whether there was a single complication given in Daniélopoli's great monograph on typhus which was not already recorded by these old writers.

The Spread of Infection

The observations of these men of a former age on the dissemination of the disease were amazingly accurate. They knew that it was spread by actual contact with the sick, and by clothing, bedding, and so forth contaminated by them, and that naked persons were less dangerous than those who wore clothing. Army physicians of the Dettingen and Fontenoy period were warned not to come into actual contact with typhus cases, but to stand at a little distance, and in examining the pulse to step forward, carefully pick up the patient's wrist, and as soon as possible step back again. They knew that typhus patients thoroughly cleansed and given fresh straw could be nursed among others without danger of contagion, and that if such measures could be instituted and maintained typhus fever would not break out. Even the role of lice as vectors of typhus was considered, and Lind (1716-94), in advocating sulphur as an efficient fumigant for typhus-infected clothing, pointed out that sulphur did not destroy lice, "from which we might be led to imagine that contagion is not propagated by animalcules." In Lind's experience, presumably, the sulphur destroyed the active forms of the lice and put an end to the disease; the more resistant eggs hatched out later, and so the clothing, although disinfected, was certainly not freed from lice.

The recommendations of Lind (who was physician to the Naval Hospital at Haslar during the third quarter of the eighteenth century) to eradicate typhus from the Navy could hardly be bettered to-day. He advocated the provision of depot ships where all men drafted to the Navy would be detained, thoroughly cleansed, and given fresh outfits. Their own clothing, if worth preserving, should be fumigated in a special smoke-room or heated in an oven: no infection, he said, could resist the heat of an oven. The men should be detained in the depot ships until the incubation period of typhus had passed—lest they should have been infected before joining the Navy—and then drafted to their ships. If Lind's counsel had been followed the Navy would have escaped the appalling epidemics of ship fever during the successive French wars, when the fleets used to go into port and land so many thousands of cases of typhus that one wondered that men enough were found to man the fleet. But Lind's voice was but a crying in the wilderness, and typhus persisted in the Navy for another half-century, in conditions summarized by Smollett, himself a naval surgeon, when he wrote that it was surprising not that the sick should die but that any should recover.

Moderns Anticipated

When these old writers forsook the guidance of observed facts for the distractions of their imagination, and entered the world of theory, they soared to transcendental heights of absurdity, but this ought not to lead us lightly to reject something which they said they had observed merely because it ran contrary to what was taught to-day. Some of their statements became intelligible to us only when our own knowledge advanced by another stage. For example, when malaria was introduced as a cure for general paralysis it was found that in the majority of patients infected by a single bite of a single mosquito the disease ran a continued course to begin with, and that the regular and disciplined attacks only occurred later. But in the reign of Charles II Sydenham wrote of intermittent fevers, as he called malaria, that they—

"do not perfectly put on their shapes, for they imitate continued fevers so well that it is hard to distinguish them. But the violence of the constitution being a little quelled, and its strength checked, having thrown off the mask they then openly appear to be intermittents, either tertians or quartans, as indeed they were really at first. And if this be not carefully

observed, we shall be deceived in our prescriptions, much to the prejudice of our patients, while we mistake fevers of this kind, which are of the order of the intermittents, for true and genuine continued fevers."

Bacot, some time before his tragic death from typhus contracted in the course of his experiments, pointed out that he had succeeded in infecting the fleas of common hens with plague, and he made the suggestion that the occurrence of the disease amongst such birds would be a great danger because of their close association with man. This brought to mind a puzzling sentence in a book entitled *Ane Breve Description of the Pest*, by Gilbert Skene, professor of medicine in Aberdeen and physician to James VI of Scotland. He wrote that this "infectioun bringis baith man and beast to death . . . and speciallie quhan the Domesticall foulis becummis pestilentielle it is ane signe of maist dangerous pest to follow."

Sometimes, however, these old observers discarded some theory which we now knew to have been correct because their experiments appeared to disprove it. During the London plague of 1665 a considerable body of opinion held that this disease was not due to a fermentation but to a living organism—"animated Matter," as they called it—which entered the body and threw off a poison there. Nathaniel Hodges carried out an investigation to try to determine the presence of this "animated Matter," but the only evidence he could find to support this theory was an account of one plague patient "who in vomiting threw up a strange figured Insect, which appeared very fierce, and even assaulted such as were busie to observe it, whereupon it was crushed by a rude Hand, so that its shape is not very discernible!"

FRACTURE CLINIC FOR SEAMEN

THE NEW ALBERT DOCK HOSPITAL

The new Albert Dock Hospital at Plaistow—one of the six for which the Seamen's Hospital Society is responsible—was opened by Queen Mary on October 21. It replaces the old building, near the same site, which was condemned as unsafe owing to soil subsidence. In its forty-seven years of existence the old hospital treated more than 375,000 patients from all parts of the world. Apart from its casualty and general hospital work, it was famous as the "workshop" of Sir Patrick Manson, a portrait of whom is in the entrance hall of the new building. Queen Mary during her visit was presented with a paper-cutter fashioned from the teak laboratory bench which Manson used. The new hospital, a pleasant, unpretentious building, has fifty-five beds, and has cost approximately £85,000. Relatively small as it is, it makes an effective contribution to modern hospital architecture.

Its outstanding feature is the fracture clinic. Owing to the number of accidents in dockland, at the gates of which the hospital stands, it was resolved to establish here a fracture clinic and rehabilitation centre as complete and well thought out as orthopaedic science can suggest. Three years ago, when the report of the special B.M.A. Committee on Fractures was published, the medical and surgical staffs of the six hospitals of the Society met and resolved that fracture cases should be concentrated at the Albert Dock Hospital, and that in their treatment the four conditions laid down in that report should be observed—namely, segregation of cases, continuity of treatment, unity of control, and after-care. The unit now installed claims to be the most complete in existence—complete in the sense that the injured man is cared for from the moment he meets with his accident until he is fit to return to his full pre-accident employment. It takes into account, for example, his nutrition. Patients discharged from the wards and continuing to attend the out-patient department and gymnasium receive their meals at

the hospital, because it is recognized that one of the most frequent causes of delayed union and continuing incapacity is under-nourishment. In order to study modern methods in fracture treatment Mr. H. E. Griffiths, surgeon to the hospital, has visited a number of American centres, including Sherman's clinic in Pittsburgh and Darrach's in New York, also Böhler's clinic in Vienna with others in Europe, not with the idea of slavishly copying anything but of ensuring that no modern method or equipment which seemed promising was disregarded.

Avoidance of Shock

The clinic at Plaistow is full of surprises. They begin, indeed, with the arrival of the ambulance, which is a specially constructed vehicle, always kept heated, and with stretchers which can be taken in and out without jerking. The ambulance actually comes into a heated bay of the hospital, adjoining which is a room equipped like a small theatre, where the patient is immediately placed in a radiant heat bath and given saline or blood transfusion as necessary. Thus within five minutes of the arrival of the ambulance all the measures required to prevent shock have been mobilized for the benefit of the patient. From the "shock room" in due course—it may be after several hours, in accordance with the needs of the case—the patient is transferred to the operating theatre or the ward. The operating block consists of two large theatres, and the feature of both of them is the x-ray apparatus adjacent to the table and the dark-room actually built into the theatre. An exposure is made during the operation, and after a matter of seconds—the actual time at the demonstration was eighty-five seconds—the large developed negative is placed in the illuminated panel of the dark-room door in the surgeon's field of view. Sometimes as many as four such exposures may be made during an operation. One feature of the theatre is a Zimmer distractor for bringing into apposition the ends of broken bones.

In the wards the beds are arranged in four pairs and four groups of four. Each bed can be shut off as a complete cubicle if necessary, and each is equipped with pulleys and facilities for every kind of movement. Adjacent to the ward is a dressing-room equipped like a small theatre to which a patient can be taken for privacy during any special dressing. The wards look out on to large sun and rest rooms, and a roof garden on to which beds can be wheeled.

The Rehabilitation Centre

The Nuffield gymnasium or rehabilitation centre, at the time of our visit, was fully occupied with men recovering from fractures, who were engaged in various forms of recreation. These men—out-patients—are invited to remain for the full working day of eight hours, which is spent largely in competitive games. A form of rowing machine has been found useful, also fixed bicycles, ladders, and the like. For five minutes at the end of each half-hour they are called into line and carry out deep-breathing exercises. Mr. Griffiths does not favour occupational therapy in this field. There is a danger, he thinks, that a man with an injured limb, if set to use that limb in avowedly occupational movements, may have his disability emphasized in his mind, whereas if he carries out substantially the same movements in recreation he loses not only the muscular stiffness but also the mental pre-occupation.

Other departments at the hospital include those for electrotherapeutics and massage. Two important non-medical members of the staff are the trainer in the gymnasium, who is a well-known former trainer of a football team and a man of inspiring personality, and the technician in charge of all the splints, apparatus, and plaster used in the hospital. The latter has visited Vienna to study the methods used by his opposite number in Dr. Bohler's clinic.

Reports of Societies

SULPHANILAMIDE: ITS USE AND MISUSE.

At the meeting of the Medical Society of London on October 24, with Dr. C. E. LAKIN in the chair, the subject for discussion was sulphanilamide, its use and misuse.

Sir WILLIAM WILLCOX said that the discovery that sulphanilamide and its derivatives had a specific antibacterial action on haemolytic streptococci was one of the greatest chemotherapeutic advances of recent years, ranking in importance with the discovery by Ehrlich of the action of salvarsan on the *Spirochaeta pallida*. In both these cases the chemotherapeutic substance did not display its full antibacterial action when acting *in vitro*; it was the combination of the drug with blood that enabled the full bactericidal effect to be manifested. The antibacterial effect of sulphanilamide was shown to the fullest extent when, in addition to an adequate blood content of the drug (1 in 10,000 to 1 in 20,000), there were also present in the blood immune substances, whether produced by active or passive immunity.

The number of derivatives of sulphanilamide on the market was considerable. He showed a list of thirteen sulphonamide preparations at present in use under different trade names. The latest was M. and B. 693 or T. 693. Sulphanilamide was of great value in all acute infections due to haemolytic streptococci. The course of scarlet fever at present was so mild that drugs were not required in the majority of cases, but in the more severe type, with complications, the sulphanilamide drugs were most valuable. Cases of erysipelas responded rapidly. Meningococcus infections cleared up in a remarkable way under treatment with sulphanilamide, and the beneficial therapeutic value of the drugs in gonococcal infection was well established. In urinary infections pyelitis and cystitis due to *B. coli* responded, but it was doubtful if sulphanilamide should usually be the primary method of attack, as the toxicity of the preparation was greater than that of mandelic acid, which latter appeared to be the more efficient antiseptic. He also referred to recent work suggesting that T. 693 (the pyridine derivative) had a definite antibacterial effect on pneumococci, especially on Types 1, 7, and 8; this effect was enhanced by the presence of immune bodies from a suitable antiserum.

Misuse of Sulphanilamide

Toxic symptoms of a mild type, Sir William Willcox continued, were extremely common when full doses of these drugs were being taken; they occurred in 50 per cent. or more of cases. The employment of sulphanilamide compounds should be reserved for cases in which the infection was due to a haemolytic streptococcus or some organism known to be vulnerable to the drug. The mere presence of a few haemolytic streptococci in the stools or nasopharynx was not an indication for their use unless there was clinical evidence that these organisms were causing the illness of the patient. Routine use in ordinary mild attacks of pyrexia, such as influenzal colds, was to be deprecated. It was important that drugs of the sulphanilamide group should be taken only under medical supervision, and therefore these drugs should be placed under the Fourth Schedule of the Poisons List, so that they could only be obtained by the prescription of a qualified medical practitioner.

Toxic symptoms of such gravity as to cause death were infrequent, but idiosyncrasy had always to be remembered and extreme watchfulness and care should be exercised. Repeated blood examinations, including red and white cell counts, should always be made if toxic symptoms

occurred. Minor toxic phenomena were extremely common, and included general malaise, nausea, anorexia, and simple cyanosis without demonstrable haemoglobin changes: more severe was the cyanosis due to methaemoglobinaemia or sulphaemoglobinaemia. Drug fever might occur after several days' administration of full doses. Grave toxic phenomena included agranulocytosis, which might be accompanied by fever, marked exudative throat changes, severe anaemia with typical alterations in the white count and disappearance of the polynuclear leucocytes, and profound toxæmia. Acute haemolytic anaemia and severe hypochromic anaemia had been observed.

Where severe toxic phenomena appeared the drug should be at once discontinued and appropriate remedies, such as blood transfusion, employed. If the blood showed no abnormal changes and a serious bacterial infection was present administration might be continued with caution, in spite of mild toxic symptoms, the aim being to produce a blood content of sulphanilamide which would assist the natural blood defences to operate on the invading infection. In such cases when mild intolerance to the drug was shown an administration over a period not exceeding three or four days was advisable, and after discontinuance for a short period the administration might, if necessary, be resumed.

Antibacterial Action of the Drugs

Professor ALEXANDER FLEMING took his "text" from a recent annotation in the *British Medical Journal* (October 8, p. 752), which raised two problems of great interest in connexion with sulphanilamide. The first was the standardization of the methods for testing chemotherapeutic drugs, and the second, the association of chemotherapy with immunotherapy. The testing of a chemotherapeutic drug somewhat resembled the examinations for medical qualification: it included two pre-clinical and a final clinical examination. The first consisted of an examination of the power of the chemical to kill or interfere with the growth of a microbe in human blood. The easiest way to do this was by the "slide-cell" technique which had been used in the laboratory at St. Mary's for many years. By this method it could be shown that sulphanilamide in concentrations of 1 in 200 had the power to damage leucocytes, and in concentrations of 1 in 128,000 to inhibit streptococci. In this first examination it was clear that the sulphanilamide group passed with honours. The second examination consisted in injecting the chemical into the body of an animal and then testing the blood at intervals for any enhanced antibacterial power. If this were done with sulphanilamide or T. 693 the blood had an increased antibacterial power which was at its height immediately after injection, indicating that the drug had a direct action on the bacteria, because if it had to be altered in the body to some antibacterial substance the change would take time, as happened with the original prontosil. The final examination was the cure of infections of man and laboratory animals by means of the drug and examination of its toxicity to the organisms as a whole. This was a question for those with more clinical experience.

Turning to the other problem raised in the annotation mentioned—the combination of chemotherapy and immunotherapy—he spoke mainly of T. 693. According to his experiments this drug had a very powerful action in inhibiting the growth of the organisms, but its actual bactericidal action was comparatively slight. This meant that the actual killing of the organism had to be done by the natural defences of the body. He showed a chart illustrating the effect of T. 693 on pneumococci in human blood with and without immune serum. With blood plus saline there were innumerable colonies; with blood plus immune serum the colonies were reduced; with blood plus T. 693 in a concentration of 1 in 16,000 there were again innumerable colonies; with blood plus T. 693 in a concentration of 1 in 32,000 plus immune

serum there were no colonies, but when leucocytes were taken out of the blood innumerable colonies reappeared.

Treatment of Pneumonia

In the light of these results it was profitable to discuss from a theoretical standpoint the treatment of pneumonia. The best results seemed likely to be obtained by a combination of chemotherapy (T. 693) and immunotherapy by means of serum or vaccine. The annotation in the *British Medical Journal* suggested that serum therapy should be reserved for severe and desperate cases, but it seemed to him that he would be a bold physician who, on seeing for the first time a case of pneumonia in a middle-aged man, was certain that it would be a favourable case for the use of only one of two powerful remedies, especially when those remedies were complementary. The grounds for withholding serum therapy in cases other than severe and desperate were that it was "expensive, difficult to administer, and apt to cause unpleasant after-effects." There was another way to induce immunity against the pneumococcus to which none of these objections applied. Vaccine therapy was cheap, easy to administer, had no unpleasant after-effects, and was available for every type of the organism. It had been shown in laboratory animals and in man—even in patients suffering from pneumonia—that after a single injection of pneumococcus vaccine antibodies appeared in from twenty-four hours to four days.

Professor Fleming suggested that in pneumonia, if the pneumococcus was of a type for which there was an effective serum, the serum and T. 693 should be given immediately; but if serum was not available, or it was not desired to give it, then an appropriate vaccine should be given, followed later—perhaps after a couple of days—by T. 693. The latter was quickly absorbed, and if the patient seemed to be going downhill it could be given and the action would be obtained within a few hours. But ordinarily it seemed better to give the vaccine and wait until there was a reasonable chance of specific immune bodies being present, and then give the T. 693. There was another reason for the delay—namely, that there was some evidence that the organism established tolerance to the drug. Therefore it was well, if possible, to withhold it until the body had acquired some immunity to the infection.

Puerperal Sepsis

Dr. EARDLEY HOLLAND discussed the work of Colebrook and his colleagues at Queen Charlotte's Hospital on the clinical value of the sulphanilamide group of drugs in the treatment of the haemolytic streptococcal infections of puerperal sepsis. He showed tables illustrating the striking improvement in mortality in 1936 and 1937, when these drugs were given, as compared with the five previous years. During 1930-5 there were 119 cases of septicaemia with or without peritonitis, with eighty-nine deaths, a mortality of 75 per cent. In 1936-7 there were thirty cases with eleven deaths, a mortality of 37 per cent. In regard to peritonitis alone in the former period there were ninety-eight cases with eighty-five deaths, and during the last two years five cases with three deaths. The drugs seemed to diminish the incidence of peritonitis as well as the mortality from it.

A number of people stated that the improvement in haemolytic infections since these drugs came into use was due to a diminution in virulence of the streptococci, and not to any effect of the drug. There was a certain amount of evidence that the organism was less virulent. Scarlet fever, for example, had become a much less serious disease than formerly. In the North-Western Fever Hospital, in which the L.C.C. cases of puerperal infection were segregated, some remarkable figures had been obtained for which he was indebted to Mr. James Wyatt. They showed the proportion of cases of septicaemia due to haemolytic streptococci.

			Cases of Septicaemia	Cases due to Haemolytic Streptococcus	Percentage
1932	18	14	77
1933	17	13	76
1934	13	9	69
1935	12	6	50
1936	13	6	46
1937	14	4	29

These figures might or might not give rise to the inference that the haemolytic streptococcus was becoming a less virulent organism, and it was a point for discussion whether the excellent results in puerperal infections with these drugs were due not only to the drugs but to a diminution in virulence of the organism.

Sulphanilamide in Gonorrhoea

Dr. G. L. M. McELLIGOTT mentioned experiences with the sulphanilamide compounds in the treatment of gonorrhoea at St. Mary's Hospital venereal diseases clinic. Over 1,000 cases had been treated with sulphanilamide and the analysis continued to show good results. They had treated 150 cases with uleron, with not such good results, and 200 cases with T. 693, which gave even better results than sulphanilamide, while proseptasine, used in a few cases, gave no lasting results at all. The treatment was divided into courses of from 70 to 80 grammes over a period of three weeks in adult males of average weight. The optimum dose appeared to be 4 grammes daily for ten to fourteen days, followed by 3 grammes daily for a further week. In the majority of cases one course sufficed to cure. Small doses appeared to be worse than useless, and seemed to make the patient abnormally resistant to further treatment even with large doses. The most important point elicited was that the correct time to start sulphanilamide was after the eighth day of the disease. A sudden improvement in the results of cases treated in the second week could only be explained by the fact that it took that length of time for the body to acquire enough immunity to deal with the organisms whose growth had been arrested by the sulphanilamide. Failures were due to premature chemotherapy, insufficient dosage and period of administration, and early interruption of the treatment. A fairly high proportion of toxic effects followed the use of the two most effective compounds, sulphanilamide and T. 693. Mild effects were shown in 50 per cent. of cases. These included slight headache and giddiness. Moderate effects—vomiting, diarrhoea, skin rashes, etc.—were seen in about 10 per cent. A few serious effects were noted, including an extensive purpuric rash.

General Discussion

Mr. WILLIAM IBBOTSON mentioned the value of anti-scarlet-fever serum given by rectum. He had treated about 100 cases with this serum in hospital. Although he had had encouraging results with the new compounds, the use of this serum, from his experience, ought not to be disregarded. Dr. P. H. MANSON-BAHR said that in the United States, which he had lately visited, "everything is being cured with sulphanilamide and prontosil." Even the small clinics seemed to be continuously employed in estimating the amount of sulphanilamide in the blood of patients. Dr. G. W. GOODHART asked how often one should make blood examinations. As one responsible for pathological investigations, if he were to do all the things he was asked to do his entire staff would be employed on nothing but blood counts. Dr. HORACE EVANS raised the question whether a case of impending agranulocytosis was due to the drug or to the original disease. Dr. C. E. LAKIN said that one very important thing about this drug was the new avenues—if that expression could be allowed—which it had opened up. Although it acted to prevent the growth of organisms and gave the body's resistance a chance to play an important part, it did not injure the tissues. He

believed that still greater achievements with drugs of this series might be expected.

Sir WILLIAM WILLCOX replied to a question on the danger of intravenous injection. It was suggested by the makers that it was not safe to give the azo dyes intravenously, but this was largely a matter of technique, and in careful hands it might be safe.

MULTIPLE CAUSATION IN PSYCHIATRY

At the meeting of the Section of Psychiatry of the Royal Society of Medicine on October 11 Dr. H. CRICHTON-MILLER, on taking the presidential office, delivered an address in which he pleaded for a consideration of multiple aetiology in psychiatry.

Dr. Crichton-Miller gave illustrations of the way in which a resultant factor, whether organic or psychic, might reinforce, or be reinforced by, a purposive or conative factor. He explained that by a resultant factor he meant any deviation from the normal which could reasonably be regarded as a manifestation of inherited characteristics or as the reaction of the organism to environmental influences, and by a purposive factor any symptom which might be taken as subserving an end, whether exhibitionism, evasion, defence, protest, or punishment. For example, the pupillary reflex was invariably resultant, but the blinking reflex might be either resultant or purposive (in other words, involuntary or voluntary), or a combination of the two.

Dr. Crichton-Miller worked out his theme by citing various syndromes in which both resultant and purposive factors appeared. For example, Freud had stated that his own slight attacks of migraine were wont to announce themselves hours before in the forgetting of names, and often at the height of the attack no proper names could be recalled. Here there were evidently two concurrent causal series: one psychic and the other organic; one a defensive adaptation, the purpose of which was to obviate affective pain, the other beginning with an unspecified psychological failure and resulting in migraine. According to Freud's statement, the intensification of the amnesia was a warning that an attack of migraine was impending; in other words, the organic sequence was reinforcing the psychic. The aetiology of migraine remained confused and obscure. In Dr. Crichton-Miller's view it could not be said with assurance that its origin was known and that that origin was purely organic in character. He left the example as a clear-cut presentation of synergy.

Psychic and Organic Factors

He next considered from the same point of view nocturnal enuresis. How far in this condition was it conceded that a purposive mechanism might coexist with a non-purposive? Might a small boy be suffering from threadworms and at the same time (according to the explanation of one school of analytical psychology which interpreted all enuresis in terms of regression to intra-uterine life) be expressing a longing to return to the uterus? In the same way, could an involutional melancholic be suffering from bacilluria and also be expressing a protest against the demands of modern life? To the speaker it seemed clear that the possibility, even the probability, of such cases of multiple aetiology must be admitted. In nocturnal enuresis there was a constant interplay between organic and psychic factors. The problem might also be studied in a case of nightmare. He found it impossible to regard nightmare as being merely stimulated by a morbid organic condition. He would rather say that most nightmares occurred as a result of somatic disturbance, while their content emerged from conative and affective patterns of the psyche. But the aetiology was left so vague as to invite a certain unwarranted assurance in the claims of the psycho-analysts.

Finally, he mentioned war neuroses. The war provided thousands of cases in which physical factors coexisted with fear resulting from war experience. He suggested that in some future war a medical officer giving a diagnosis of war neurosis would be asked to answer how far he supposed that a defence mechanism, conscious or unconscious, entered into the case, how far toxic factors were contributing, how far he considered the man constitutionally incapable of rendering adequate service, and what disposal he recommended—rest with isolation, with distraction, or with occupation, services of a psychotherapist, reclassification, or discharge. Dr. Crichton-Miller concluded:

"What is true of the war neuroses is true of the neurotic disabilities of civilian life. At every point disability, whether resulting from biological or affective causes, is liable to be pressed into the service of a personal aim. . . . What matters to us is that with most of our patients the past and the future are continually in mesh, and no real advance can be made in psychiatry except by those who are sensitive to this constant interaction."

MARINE THERAPEUTICS

At a meeting of the Section of Physical Medicine of the Royal Society of Medicine on October 21 a discussion took place on marine therapeutics.

Dr. K. R. COLLIS HALLOWES of Torquay, who took the chair as the new president of the section, said that classification of the many various marine climates of the British Isles was difficult. Many marine resorts had local characteristics which caused them to differ from other resorts in the same regional group. Conclusions drawn from meteorological data alone might be erroneous. Moreover, individuals reacted in different ways to the same meteorological factors. Some were more weather-sensitive than others, some reacted abnormally but could be re-educated to more normal responses. Marine climates differed from inland climates in various ways. Sun-bathing and sea-bathing were of considerable therapeutic value, but were often abused, and there was need for their careful prescription during convalescence and for therapeutic purposes. Sea-water was a natural mineral water and might be used for all hydrological procedures. Reactions following its use were very similar to those following the use of other waters. The future development of marine resorts for therapeutic purposes required consideration and medical direction, and further research work was essential.

The British Coast-line

Dr. S. WATSON SMITH of Bournemouth divided the climates of Great Britain into two physiological groups: (1) the stimulating, tonic, or bracing, suitable for those needing toning up after illness or operation; (2) the sedative and relaxing, inducing rest of body and mind. Smaller and less artificial places than the popular resorts had a curative value for many. Much had yet to be done in collecting and verifying information on climate; this might be done county by county by local medical men. The "seaside" should include a littoral to embrace valleys and terraced levels rising from the sea. Sea level or propinquity to the sea was not always desirable.

The east coast of Scotland was to be recommended, during the late spring, summer, and early autumn, for the robust after illness or operation; only in midsummer for the delicate. During fine weather it was indicated for hypopiasis and neuro-circulatory asthenia.

The east coast of England was useful, in the warmer months, for nervous disorder and disease, especially about middle age; also in convalescence after respiratory catarrhs

and inflammations, in chronic bronchitis and emphysema, bronchitic asthma, and post-influenzal weakness. Contra-indications were hyperpiesis, hyperpiesis with chronic kidney disease, advanced arteriosclerosis, and polycythaemia.

The south-eastern region (Kent and Sussex, to Hampshire) was desirable for delicate children and adults at all seasons, particularly for the young with tuberculosis of bones and joints; also after spa treatment in non-specific arthritis, fibrositis, neuritis, and neuralgia. During the summer it was useful in cases of chronic bronchitis, emphysema, bronchiectasis, pulmonary fibrosis, and disease of circulatory system; contraindications were high blood pressure, thyrotoxicosis, and plethora.

The southern region was to be recommended all the year round in the neuroses, insomnia, thyrotoxicosis, high blood pressure, granular kidney, and chronic respiratory disease, including tuberculosis. In summer the delicate did not do so well on this coast; but at all times children convalescent from juvenile rheumatism did well, as did children with asthma. This was a good coast for permanent residence for those struggling against ill-health.

The south-west coast was indicated for subacute and chronic bronchitis, sinusitis, arteriosclerosis, aneurysm, arterial hypertrophy, angina pectoris, degenerative myocarditis, high blood pressure, and senility; contraindications were low blood pressure, and in the case of sick children except at the beginning of convalescence. Patients with arthritis often did well on the Somerset coast.

The north-west coast was for debilitated persons with functional derangements, emphysema, persisting sinusitis, bronchitis, laryngitis, or rhinitis, and sufferers from delayed recovery after acute illness. Except during fine weather, this coast was better avoided; contraindications were fibrositis, any form of arthritis, and subacute and chronic bronchial trouble.

Sir HENRY GAUVAIN dealt with the marine treatment of surgical tuberculosis and septic bone conditions. He said that he had explored the south coast from the mouth of the Thames to the mouth of the Severn to find the best place for the establishment of the marine branch of Alton. He wanted warmth, abundant sunshine, low level, clear air, flat littoral, sheltered position, and south aspect. He found only one place which had all the desiderata, and that was Hayling Island. Some children, those with pronounced cachexia, were not strong enough to respond to sea stimuli. He and those associated with him at Alton could now instantly determine by looking at the children those suitable for marine treatment. It was the child with good powers of resistance and able to respond to stimuli who would do well. A few days were spent by the children in getting acclimatized, and then paddling was started, later spraying, and finally complete immersion.

In the course of discussion Sir Henry Gauvain was asked to compare his results with those of Rollier at Leysin, and he said that he thought results were more quickly obtained at Hayling Island, but statistical comparisons were fallacious, because most of Rollier's patients could come and go when they liked, whereas the Alton children were hospital patients who remained for their cure. The time taken depended on the constitution of the child, the average for the crippled child was from fifteen to eighteen months.

Dr. M. B. RAY asked what was the effect of sea-water in giving massage douches. Sea-water was probably the hardest water imaginable, and he wondered how the hands of the operator could utilize the hard liquid in giving massage which required relaxation of muscles and a soapy kind of water. Dr. COLLIS HALLOWES said that his experience was that massage could be quite effectively given with sea-water and the results were very satisfactory. He had never heard attendants complain of the effect of sea-water on their hands, and it was exceptional to find any irritation of the skin following Aix or Vichy douches for which sea-water was used.

YELLOW FEVER

A meeting of the Royal Society of Tropical Medicine and Hygiene was held at Manson House on Thursday, October 13, when Dr. FRED L. SOPER of the International Health Division of the Rockefeller Foundation for South America gave an address entitled "Yellow Fever: The Present Situation, with Special Reference to South America." The president of the Society, Lieutenant-Colonel S. P. JAMES, was in the chair and the meeting was attended by His Excellency the Brazilian Ambassador.

Activities of the Rockefeller Foundation

Dr. Soper related how the Rockefeller Foundation embarked in 1915 on a programme of eradicating yellow fever from the Americas by collaborating in the organization of measures directed against the insect vector—*Aedes aegypti*—in the known endemic foci of the disease. These measures strikingly reduced the number of cases in the larger cities and ports, but failed to eradicate the disease completely from certain areas in Brazil. That this was not characteristic of Brazil was suggested by the occurrence in 1929 of two widely separated outbreaks at isolated points in Colombia and Venezuela, and it was ultimately shown that there were two hitherto unknown factors to be considered—namely, rural yellow fever transmitted by *Aedes aegypti* occurring in a localized area of North-East Brazil, and jungle yellow fever, which was widespread and occurred in the absence of *Aedes aegypti*. The rural type was bound up with the nomadic habits of the people, who moved freely from place to place during pilgrimages and periods of drought, and carried with them in their water-jars eggs and larvae of *Aedes aegypti*, which readily found new breeding-grounds in the stores of rain-water collected against the drought. When these facts were determined, extensions of the preventive service to the rural areas produced results similar to those obtained in the cities, and yellow fever rapidly disappeared from the regions in which this work was undertaken; in fact, were it not for the existence of the jungle infection, yellow fever might well have disappeared from the Americas in 1934.

The epidemiology of the jungle infections was, however, quite different from that of the other types, although, clinically, the diseases were exactly similar. Urban and rural *aegypti*-transmitted yellow fever was generally acquired indoors; tended to involve non-immune persons of all ages; was spread along the lines of human travel; and was easily controlled by reduction of the density of the vector. Jungle yellow fever, on the other hand, was acquired in or near the forest during working hours by those whose occupation took them to the woods, and did not involve other members of the household. The infection of man was apparently accidental, occurring in the course of some cycle of infection of which man was not an essential part. Recently forest mosquitos (*Aedes leucocelaenus*, *Haemagogus capricorni*, and species of *Sabethes*) had been captured and shown to be naturally infected, and, furthermore, there was some evidence that certain monkeys commonly became infected. It was difficult, however, to fit all the observed facts into a simple mosquito-monkey-mosquito cycle of which human infection was but an accidental offshoot.

In the face of this problem the only reasonable hope of preventing human infection seemed to lie in individual immunization of exposed populations. During the first nine months of 1938 more than 800,000 persons had been vaccinated with entirely satisfactory results and without serious complications of any kind. Dr. Soper emphasized the valuable knowledge that had been obtained from examination of livers obtained by viscerotomy, the service which he had organized having made over 140,000 examinations. He stated that viscerotomy, anti-*aegypti* measures, and vaccination were the keys to successful control of yellow fever in Brazil. His Excellency the

Brazilian Ambassador then spoke of the happy co-operation between the Federal and State authorities and the Rockefeller organization.

Mouse-protection Test

Dr. G. M. FINDLAY showed how the mouse-protection test had revealed the unexpectedly enormous endemic distribution of yellow fever in Africa. There the disease was both urban and rural, but jungle yellow fever in the Brazilian sense had not been demonstrated in Africa, as so far no rural area had been found in which *Aedes aegypti* was not present. Hepatitis, which in some cases followed the earlier vaccinations, was due to another virus, probably similar to, or identical with, that of epidemic catarrhal jaundice, which had been introduced accidentally into the yellow fever tissue culture. This complication had now been eliminated. Judged by blood tests, immunity lasted two or three years, but tissue immunity might persist longer.

Dr. M. T. MORGAN asked whether the mouse-protection test and the liver examinations could be regarded as satisfactorily specific, and Colonel F. P. MACKIE mentioned that the results obtained by the mouse-protection test suggested a recent silent spread of the disease around Mallakah in Africa, although there was a strange absence of clinical evidence of the disease. Sir JOHN MEGAW raised the question whether the virus, if introduced into India, would spread as in Africa and America. Sir MALCOLM WATSON admired the organization for the control of *Aedes*, and expressed the hope that the details would soon be published. With regard to the spread of the disease in Africa he had failed to find *A. aegypti* breeding in trees in Nigeria.

In reply, Dr. SOPER stated that he had every confidence in the mouse-protection test and the pathological examination of the liver as indicators of infection. Jungle yellow fever, he believed, was the older and more permanent form of the disease. With regard to Africa, he thought that if the virus ever reached the east coast the worst might be expected, since every boat headed for India would threaten extension of the disease to that country.

ESCAPE INTO INVALIDISM

The Medical Society of Individual Psychology has arranged for a series of papers upon the subject of psychological "escapes" to be given during the present session. At the first meeting on October 13, with Dr. H. C. SQUIRES in the chair, "escape into invalidism" was discussed.

Dr. GEORGE GORDON read a brief paper to open the discussion. He suggested that it would help to keep the discussion within manageable bounds if the following types of cases were excluded—namely, malingering, anxiety states, and valetudinarianism in elderly people if it occurred as an accompaniment of organic senile changes in the cerebral cortex. He also excluded hypochondriasis properly so called as representing a psychotic illness with delusion, which would be dealt with later in the session. He believed that the profession now recognized the psychogenic origin of hysteria, but drew special attention to another numerous class of patients, who were best described as people who "enjoyed ill-health." He took as the classic prototype of such patients *Le Malade Imaginaire* of Molière, and pointed out that there is no evidence that Argan in this play is the subject of hypochondriacal delusions. He quoted passages indicating Argan's overweening desire to dominate the household in a multitude of ways, and his constant desire to have members of his household perpetually at hand to help him. Argan's constant ailing was a device whereby he achieved assurance that infallible assistance, as represented by the medical profession, would be available at all times. Dr. Gordon pointed out that *le malade imaginaire* was a man imbued with a sense of insecurity

and inadequacy to meet what he believed to be the demands of life. Many people who were reputed to "enjoy ill-health" were persons with a sense of inadequacy. In Dr. Gordon's experience such people were often not endowed with much physiological vigour. Nothing was gained by pooh-poohing the possibility of imperfect health in such cases. . . . "As physicians we can be of the greatest value to such persons by helping them to understand themselves, so that they may face their task in life with such physiological endowment as they possess. We can also encourage them to abandon the desire to achieve a sense of adequacy and security by the domination of others through their own invalidism."

Mental and Physical Pain

Sir WALTER LANGDON-BROWN, in complimenting the opener on the way in which he had defined the issues, brought forward some evidence that the "mollusc" type of escape into invalidism was often subconscious. On another occasion he had defined as necessities for happiness the possession of a definite goal and an emotional interest. When either or both of these were frustrated there was a tendency to compensate by this method of escape. Hippocrates said, "Of simultaneous pain in two places the lesser is obliterated by the greater." Few would doubt that mental pain could be greater than physical pain. Certainly medical men were constantly seeing instances where patients sought a physical pain as a relief to mental pain, for the former could be talked about and would excite sympathy; the latter they preferred to bury in their own bosoms. Then came the magician offering new lamps for old in the form of new pains for old and pains that could be talked about. Physicians should be constantly on the watch for these substitute pains and should seek for the underlying mental or emotional cause. It was clear that in many instances an escape into invalidism enabled the individual to dominate the situation through weakness. Another factor inducing such escape was indecision, for as long as ill-health existed the necessity for solving a problem could be postponed and conflicting factors could be held in balance. A number of cases were reported which illustrated these contentions.

Motivation of Neurotic Illness

Dr. W. R. REYNELL said that the conception of neurotic illness as an escape was no doubt true in many cases, but in others it was a passive negative refusal to co-operate owing to a sense of grievance or other motives. In some the motive of neurotic illness might be regarded as a wish to fall ill as an expression of some unconscious feeling rather than as an escape from something—a wish for self-punishment, self-aggression, as an effort to atone for unconscious feelings of guilt dictated by an infantile conscience. Adler had said that every neurosis could be understood as an attempt to free oneself from a feeling of inferiority in order to gain a feeling of superiority. Did this conception of neurotic behaviour always explain the motives which led to anorexia nervosa, self-inflicted injuries, and even suicide, or states of morbid depression and suffering following loss and disappointment? Neurotics, according to Adler, had sought power and freedom from responsibilities to others; but there was another type very liable to fall into neurotic illness—the peace-loving, gentle, often physically timid and easily discouraged person. Dr. Reynell did not think that the "wish to fall ill" was the same as "an escape into illness."

The escape into nervous invalidism implied the adoption of a bad "style of life," the "pursuit of an inferior goal"—the expression of an "inferiority complex," as Adler described it. Many such patients might be described as "evasive compensators," who evaded difficulties and responsibilities and developed neurotic symptoms instead. The subsidence from, or refusal to rise to, a normal adult state of social co-operation and usefulness

might occur at all ages and might arise from the withdrawal of a stimulus or from disillusionment. The type of neurotic invalidism might be determined by (1) "organ inferiority": damage from organic illness or hypogonadism (hysterical symptoms often followed on organic illnesses); (2) the results of operation or accident; or (3) the symptoms might be symbolical of a state of mind. Whatever the symptoms were, the following had to be determined: (a) *Why* did the patient fall ill? (b) *Why* did the patient fall ill *when* he did, or, as Adler put it, "What shocked him"? (c) *Why* did the patient fall ill *in the way* he did?

Dr. EDWARD F. GRIFFITH suggested that life was more difficult in these days and there was a greater tendency to try to escape from responsibilities. This was particularly noticeable in the refusal of many of the younger generation to have children. The older general practitioners were often certain that there must be a physical cause for neurotic illness even if every method of examination had failed to discover it. Often it was extremely difficult for the physician to assess the various factors of causation. He gave examples of neurotic types of illness seen in general practice where either the psychological or the physical origins were finally discovered. In women patients neurotic illness was often made the excuse for a refusal of conjugal relationship or for purposes of domination. The sex life of many married women was unsatisfactory. The cause was not always originally psychological; often it was due to some minor or major physical disability that could be remedied, particularly in cases of frigidity and dyspareunia. He thought that in such cases there should be more co-operation between psychologists and those doctors who made a specialty of sexual disabilities. He mentioned the necessity for inquiring as to the practical expression of emotional feeling—the question of sex technique. An interesting discussion followed in which many members of the Society took part.

maximum of sunlight and cross-ventilation obtained. The crossbar of the H forms on the ground floor an entrance hall walled with glass bricks and very attractive in appearance. It is approached by a ramp, a piece of thoughtfulness for the large proportion of users of the centre who will be sufferers from some physical disability. With the same object all the clinics are on the ground floor and accessible from airy, well-lighted corridors, so planned as to avoid the tunnel-like effect of many such passage-ways. One upright of the H contains the tuberculosis clinic, including consulting-room, surgery, laboratory, and x-ray department, with special accommodation for artificial pneumothorax treatment. The opposite upright contains the women's, dental, and foot clinics. On the first floor are lecture hall, administrative offices, and reception wards, separated by a common kitchen, for men and women who are temporarily de housed for sanitary reasons. The disinfecting and cleansing stations are in the basement with separate access from the rear. Many interesting details take the attention, such as the large continuous ranges of windows, the radiant heat panels concealed in the ceiling, the reinforced concrete walls lined with cork slabs to afford sound and heat insulation, the facing of the concrete with tiles of pale cheerful tints, the open forecourt laid out with grass and shrubs, and the roof terrace. The planning has been such as to allow for all possible flexibility in the disposition of the rooms, and if rearrangement of departments or the installation of fresh equipment becomes necessary partition walls can be removed without major structural alterations. The building has been designed by Messrs. Tecton, the architects responsible for the new buildings at the Zoo and at Whippsnade, and many of the ideas incorporated in the enterprise owe their origin to the chairman of the public health committee of Finsbury Borough Council, Dr. C. L. Katial. The centre is in Pine Street, close to Farringdon Road, and only a short walk from Finsbury Town Hall.

Local News

ENGLAND AND WALES

Finsbury Health Centre

The new health centre of the Finsbury Borough Council, which was opened by Lord Horder last week, is an interesting departure, from an architectural point of view, among institutions of this kind. It represents a break-away from traditional municipal lines; a design has been worked out on the pavilion principle, having in view no other consideration than the needs of the various public health services to be controlled and organized in the building. These services are a dental clinic, a tuberculosis dispensary service, to which is attached an x-ray department, a solarium for ultra-violet ray treatment (to be given to adolescents or adults requiring it, upon the recommendation of a practitioner), a foot clinic (a new venture, set up in view of the widespread disability arising from minor ailments of the feet), and a clinic for diseases, again of a minor character, peculiar to women, for which there has been up to now no special provision in the borough. The building will also include cleansing and disinfecting stations, a mortuary, and a bacteriological laboratory for the diagnosis of infectious and contagious diseases, the examination of milk, and the like. Thus there will be accommodated under one roof all the health services administered by the local council with the exception of maternity and child welfare. There are two maternity and child welfare centres in the borough, both in comparatively new premises and advantageously situated with regard to the areas they serve, and it has been decided to leave them where they are.

The building corresponds to a wide letter H: by this means congested approaches have been avoided and a

St. John Ambulance Brigade

The second annual week-end conference of the surgeons of the St. John Ambulance Brigade was held in London on October 15-16 under the presidency of Dr. N. Corty Fletcher, surgeon-in-chief. All districts of the Brigade were represented, including the Priory for Wales and the Irish Free State. Considerable attention was paid to matters relating to the Brigade's work in connexion with the A.R.P. and the local anti-gas certificates. Some aspects of competitions came up for consideration, as did also the revised *Textbook* with demonstrations of loading the stretcher face downwards. The subjects for discussion included diabetic coma, the issue of certificates, the promotion of surgeons, and the general regulations. The guest of honour at the annual dinner on the first day of the conference was Sir Herbert Creedy, G.C.B., K.C.V.O., Permanent Under-Secretary for War.

Research at Birmingham

The City and University of Birmingham Joint Board of Research for Mental Disease has continued its unspectacular but useful work during the past year, and its annual report sets out the progress that has been made. Several more thick sections of brain have been examined for capillary irregularities and the findings correlated with the clinical diagnoses. Work has been started on the relation of chronic septal infections to cerebral capillary irregularities, and a number of brains have been examined after Gram staining. As was to be expected, Gram-positive organisms were found in a few cases only. There is some evidence that Gram-positive organisms lose their positive character after many days, and examinations are now being made of sections of brain stained to show Gram-negative organisms. The capillary stain technique showed areas of ischaemia in nearly all and areas of congestion in the greater proportion of cases. Many specimens also showed haemorrhages, thromboses, or perivascular granules. An endemic

clinical and subclinical dysentery caused a large increase in the total number of specimens examined in the laboratory. Out of 2,037 specimens of faeces examined for typhoid-dysentery organisms, abnormal organisms were isolated in 1,992. The special care which the results indicated is believed to have averted an epidemic. A large number of supposedly non-pathogenic salmonellas were found, especially in the clinical dysentery cases. Aberrant coliform organisms were high in the dysentery cases and below average in the typhoid carriers. Another interesting point is the low incidence of streptococci in the typhoid carrier cases as compared with the average. The research work of the Board is now in process of being transferred from Hollymoor to the new Medical School of the University. When the transfer is complete it is anticipated that Dr. Stanley Barnes, Dean of the Medical Faculty, will take up the position of Honorary Director of Research and Chairman of the Advisory Board.

An Old Medical Charity

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on October 12, with Mr. V. Warren Low, president, in the chair. The audited accounts for the half-year ended June 30 were presented and approved. From them it was shown that £2,210 had been distributed in grants among the sixty-one widows and five orphans in receipt of relief. The income for the half-year amounted to £2,979, and £250 Consols at 2½ per cent. had been purchased. It was decided that a Christmas present of £5 be made this year to each widow and orphan in receipt of grants, entailing an expenditure of £330. A donation of £2 2s. had been received from the South-West London Postgraduate Association. Grants amounting to £2,208 were voted, subject to the approval of the visitors, for the payment of the half-yearly grants due on January 1, 1939. On October 29 the society celebrates its 150th anniversary, and it is probably one of the first, if not the first, medical relief society to be established. It was founded in 1788, and two members of the same family, father and son, have been secretaries for seventy years. Membership is open to any registered medical man who at the time of his election is resident within a twenty-mile radius of Charing Cross. Election is by ballot. Full particulars and application forms for membership may be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, W.1.

SCOTLAND

Vital Statistics for Scotland

The report of the Registrar-General for Scotland for 1937 shows that the estimated population at the middle of the year was 4,976,600, of whom 2,396,900 were males and 2,579,700 were females. The population has increased since the census of 1931 by about 133,600 persons, mainly attributable to excess of births over deaths. The number of births registered during the year 1937 was 87,810, including 45,035 males and 42,775 females. This gave a birth rate of 17.65 per 1,000 of the population, slightly less than in the previous year and the lowest recorded except for the year 1933, when the rate was 17.62. The highest birth rate recorded was in 1876, when it was 35.62; since then the general trend with minor fluctuations has been steadily downwards. Deaths registered during the year numbered 68,942, giving a rate of 13.85 per 1,000 of the population. The general trend of the rate has, until the last three years, been steadily downwards, from 23 per 1,000 in 1864 to 12.92 in 1934; since 1934, however, each year has shown a slight increase. The standardized rate shows a direct relation to urbanization, for it was 12.36 in landward areas, 12.95 in small burghs, and 15.08 in the large burghs. Deaths of children under 1 year numbered 7,050, giving an infantile mortality rate of 80.3 per 1,000

births, a diminution of 2.0 as compared with that of the previous year. With regard to causes of death, the principal epidemic diseases accounted for 4,468 as compared with 2,719 in the previous year, the increase being attributed chiefly to an epidemic of influenza in January and February, and to an increase in the number of deaths from whooping-cough. Deaths from diphtheria numbered 426, giving the same rate as before. Scarlet fever, with 123 deaths, and measles, with 119, both showed substantial decreases. Tuberculosis accounted for 3,663 deaths with a death rate the same as for 1936 and 1935. Deaths from malignant disease numbered 7,810, giving a rate slightly less than that for the previous year but slightly more than the previous five years' average. Diseases of the circulatory system accounted for 15,732 deaths, and it is pointed out that in eleven years they have increased from 7,375 to this figure, the largest increases being at ages over 65. Diseases of pregnancy and childbirth numbered 424, being 70 fewer than in the previous year, while deaths from puerperal sepsis, numbering 144, were 51 fewer than in 1936. Deaths from all puerperal causes gave a rate of 4.8 per 1,000 births, of which the rate for sepsis was 1.6.

New Aberdeen Professor

Dr. Robert Stevenson Aitken, F.R.C.P., has been appointed Regius Professor of Medicine in the University of Aberdeen in succession to Professor L. S. P. Davidson, resigned. Professor Aitken is of Scottish parentage and was educated in New Zealand, where he graduated M.B., Ch.B. at the University of Otago in 1923. After acting as house-physician and house-surgeon in Dunedin Hospital he was a Rhodes scholar at Balliol College, Oxford, in 1926. Later he became assistant pathologist in the London Hospital, and assistant physician to the medical unit, London Hospital, in 1930. Since 1935 he has been University reader in medicine and assistant director of the medical department in the British Postgraduate Medical School, London.

Crichton Royal Institution, Dumfries

The directors of this well-known mental hospital on October 18 opened an important addition to the institutional buildings in the shape of an extensive centre, Easterbrook Hall, erected for recreational and therapeutical purposes. The structure, with equipment and furnishings, has cost about £60,000, and contains, in addition to a large hall in which there is a stage and cinema installation, separate sections in which are housed operating theatre, dental surgery, accommodation for x-ray and other electrical treatment, a hydrotherapy section with baths and swimming pool, fully equipped gymnasium, arts and crafts section, hairdressing saloon, library and reading room, and tea room; also facilities for sun-bathing. Dr. M'Cowan, the medical superintendent, said that they were learning the value of recreation and occupation in mental cases, and also how to apply physiotherapy and electrical and light treatment. The primary aim of physical medicine was to build up the patient's physique and defensive mechanism, and psychiatrists had found that this was useful not merely in physical disease but also in nervous and mental disorders. Dr. C. C. Easterbrook, after whom the new building is named, performed the opening ceremony. He said that there had been numerous additions to the institution since the foundation stone of the original Crichton Hall was laid in 1835. Modern hospitals, villas, and nurses' homes had been added as well as the Crichton memorial church in 1897, and, later, a model home farm with tuberculin-tested herd, an artesian water supply, an electric light and power installation, and pathological laboratories. All these had placed the Crichton Institution in a unique position among mental hospitals. The institution comprised three separate departments with distinctive hospital observation and convalescent sections, still further subdivided into units. This enabled a proper classification of patients, which was the first step in all treatment, to be a special feature at the Crichton

Royal Institution. The latest addition for the more specialized forms of physiotherapy and psychotherapy would render the institution unsurpassed in the amenities it offered.

Edinburgh Nursing Scheme

The Scottish Council of the Queen's Institute of District Nursing has devised a scheme of nursing benefits for Edinburgh which began on October 24. There is already in operation a home nursing contributory scheme established by the Institute in 1925 with a membership of over 30,000 in Edinburgh, including employees in factories, shops, offices, and warehouses, who may join in bodies of not less than five persons at an annual subscription of 2s. 2d. paid at the place of employment. The new scheme enables other persons to join individually at a subscription of one penny per week, or 4s. 4d. per annum, which is collected at the place of residence. This subscription entitles members to nursing benefits for themselves or for non-wage-earning dependants, but not to maternity nursing or attendance at operations, which, however, can be obtained for a small additional fee. As regards arrears in payment, the member is out of benefit if more than six weeks without payment have elapsed, but may return to benefit fourteen days after paying the arrears; after twelve weeks without payment membership lapses, although the member may rejoin, but not during an illness. The scheme is not intended to apply to persons who are in a position to employ a private nurse, although persons above the income limit may obtain the nursing service for their indoor domestic staff on payment of 10s. annually.

Glasgow Post-graduate Courses

The winter session of the Glasgow Postgraduate Medical Association opens next month. A series of weekly demonstrations for practitioners on Wednesday afternoons will open at the Stobhill Hospital on November 2, when Professor Noah Morris will speak on deficiency diseases. The demonstrations, covering a wide range of subjects, have been arranged on similar lines to those of previous years. The fee for the course is three guineas. Courses have also been arranged at the Glasgow Eye Infirmary for those interested in ophthalmology, and facilities for the study of clinical obstetrics and ante-natal work are offered by the Royal Maternity and Women's Hospital. A practical course on refraction will be given at the Ophthalmic Institution. A course in radium therapy is offered at the Glasgow and West of Scotland Radium Institute, and at the Glasgow Royal Cancer Hospital if a sufficient number enrol. A course of lectures in psychopathology, with special reference to the neurotic illnesses of children, will be given at the Royal Mental Hospital, Gartnavel, on Mondays at 8 p.m., from January 16 to March 20, 1939. The fee for the course is two guineas. A limited number of clinical assistantships are available at most of the institutions taking part in the work of the association during the winter months as well as at other times of the year. Full particulars can be had from the secretary, Postgraduate Medical Association, the University, Glasgow.

Glasgow University Graduation

Sir Hector Hetherington, the Principal of the University, presided at the graduation ceremony at Glasgow on October 16 and conferred the degree of Doctor of Medicine upon three graduates and those of M.B., Ch.B. upon 103 graduands. In his address he said that the September examinations had taken place during a time of anxiety and strain, and the examiners had been surprised at the remarkably high level achieved by candidates working under such conditions. This showed steadiness of nerve. They now had an assured place in the work that lay ahead, and the opportunity of doing what they could for the safety of this country and its honourable duty in working towards a happier state of international relations.

Correspondence

Civil Medical Organization in War

SIR.—In the recent crisis I, like many others, could not help reflecting upon the personal effect which war, had it come, would have produced, and contrasting this with the outlook at the beginning of the last war. In August, 1914, I was a subaltern in one of the batteries of the H.A.C., and throughout the war I served in the Artillery. In 1914 I entered the war feeling confident that the careful preliminary training through which I had passed would be put to good purpose, and was stimulated by this thought. During the recent crisis, however, the certainty that my professional services would be called upon to the full as soon as war began brought only a sense of overwhelming bitterness. The number of dead and wounded for whom provision would have had to be made has not been publicly stated, but would run into very many thousands in every twenty-four hours, at any rate until a large portion of the population had been evacuated, and for every person wounded there would be one dead. In France and Flanders we were always supported by the feeling that every man in the field was contributing something to the common task. In September, 1938, I could see ahead of me only unending hours spent in rooms filled with operation tables, attempting to repair the terrible wounds produced by bombs. The patients would not be soldiers whose sufferings were to some extent balanced by the losses they had just inflicted on the enemy, but civilians whose very presence in London would be an encumbrance, and in most instances only make the maintenance of its essential services more difficult.

It seems likely that the call which war will make upon the medical profession in London and other of the more vulnerable cities will be greater than upon any other class of the community, only excepting those who will fight in the air. Our numbers are very limited and the task imposed upon us will be immense. Surgical and medical treatment will have to be carried out unceasingly and under conditions far more exacting than any experienced in the last war. Rest during such periods of off duty as are available will be broken by air raid warnings proclaiming the need to be "alert," and even if we could grow enough accustomed to these to ignore them, the noise of gun fire and bomb explosions would make sleep impossible. While the earning of a livelihood by private surgical practice in London will have passed away, our duty to the public will compel us to remain. Dr. Clement Francis in the *Journal* of October 22 (p. 862) draws attention to the uselessness of providing "... the most efficient medical service conceivable if the number of casualties is going to be tens of thousands, all occurring in the space of a few minutes." I believe that it is the duty of the medical profession to spare no effort to convince the public of the very urgent need to plan, first, the speedy evacuation from London of all whose presence is not essential, and, next, protection for those who of necessity must remain, for London will indeed be the front-line. Unless this can be done the casualties are likely to reach proportions which will completely overwhelm the medical services, many of the wounded will be left for long periods untreated, and the dead unburied. The construction of adequate roads leading out of London, and of shelters within it, should be begun at once.—I am, etc..

R. OGIER WARD, D.S.O., M.C., F.R.C.S.

London, W.1, Oct. 24.

Air Raid Precautions

SIR,—The lesson we as doctors should learn from the present A.R.P. muddle is the futility of working as individuals, or even as hospital units, and the absolute necessity for a central controlling organization to correlate our work.

If war comes it will be the civilian who will be in the front line, and therefore it is the well-proved methods of military evacuation of wounded that ought to be provided for the civil population. Those of us who went through the war are familiar with the long chain of units from first-aid posts in the immediate fighting area to base hospitals far from the centre of attack. It is an organization like this we require for the civil population in any future war. Sir Frederick Menzies makes this quite clear in his letter (*Journal*, October 22, p. 860). As he points out, anyone with practical knowledge of administration knows that there must be "unit control"; in other words, some one central authority must have control of aid posts, ambulance service, and hospitals. This central authority must staff and control all the hospitals, voluntary and municipal, and this authority must apportion the casualties to the hospitals so as to prevent overcrowding or undercrowding.

An attack on a great city like London should be visualized as a battle. There will be the dead; there will be the dangerously wounded; there will be the slightly wounded; and, as in any battle, the slightly wounded will vastly outnumber the rest. It is they who will flood the hospitals if not prevented. Even in the war, with disciplined men, it was not easy to avoid this. All casualties should be sorted out at the aid posts, and these aid posts should be in bomb-proof shelters and properly staffed. Hospitals in the great cities should be clearing stations only. No one in the war ever thought of keeping casualties in the front line. London and all great cities in future wars will be in the front line.

The idea of concentrating numbers of highly skilled men in the great teaching hospitals to handle casualties is absurd. No hospital will be immune from attack. It takes ten years to make a surgeon, and to risk a concentration of technical ability in any building that is vulnerable is doing a disservice to the public.

The experience of Barcelona has shown that a panic evacuation of the civilian population is not necessary if bomb-proof shelters are made. Dr. Clement Francis has pointed out in your columns (October 22, p. 862) that if such shelters are provided now the problem of evacuation is solved. Such shelters would immensely minimize the percentage of casualties in an attack. Such shelters should be provided with aid posts adequately equipped to handle all casualties as they occur, and to evacuate such as need further treatment to hospital. If, then, we had a proper central organization to collect and evacuate casualties from these aid posts we could face air attacks in the future with comparative equanimity.—I am, etc.,

J. JOHNSTON ABRAHAM,
Formerly A.D.M.S., Lines of Communication,
Egyptian Expeditionary Force.

London, W.1, Oct. 22.

SIR,—I absolutely agree with Dr. Clement Francis's letter on air raid precautions. Prepare hospital accommodation of course, but try to prevent there being much need for it by providing sufficient bomb-proof shelters. The effect of the modern high-explosive bomb is devastating, and, in my opinion, the casualties from gas would be negligible by comparison. The only gas that

caused really heavy casualties with a big mortality during the war was chlorine released from cylinders, which could obviously not be used against our civil population. No country is going to bomb with gas extensively when high explosive would cause ten times the damage. I think that the issue of gas masks in remote country villages is a waste of money which should be spent on providing deep shelters for everyone in our large cities.—I am, etc.,

Colchester, Oct. 22.

CYRIL HELM.

Protection Against Gas Poisoning

SIR,—Recent circulars relating to air raid precautions and the use of gas masks emphasize the point that the latter do not protect us against the poisonous effects of common coal gas. It is further pointed out that infants for whom no gas mask is available may be wrapped in a blanket and carried safely in this way through the dangerous zone. The following personal experience not only supports this last statement but goes further and shows that the blanket will also protect against coal-gas poisoning.

In 1902 I was acting as a district medical officer and was also engaged in general practice in a suburb of London. I attended a patient in her confinement, and four months after this event I was summoned urgently to this patient's home to find her and a boy and girl of 6 and 8, respectively, dead in various parts of the room owing to gas poisoning from a leaky meter, but the baby of four months was lying in the bed covered by blankets. The infant was still alive, and suffered no ill effects.

At the subsequent inquest the coroner asked me how I explained the infant's escape, but he disagreed with my suggestion that the blanket performed the function of a filter or mask. It would be interesting to ascertain whether the wool of the blanket is an important factor in these circumstances, and whether an equal thickness of cotton or silk cloth would afford similar protection. It should be possible for chemists engaged in gas warfare work to supply the answer.—I am, etc.,

London, W.1, Oct. 20.

JOHN F. O'MALLEY.

Modern Decline of Breast-feeding

SIR,—I read with much pleasure the valuable paper by Dr. J. C. Spence in the *Journal* of October 8. I hope it will not only be read but digested by those working in nursing homes, maternity hospitals, and teaching centres. In the course of many years' attendance at an infant welfare centre, mothers sent from institutions have often stated that breast-feeding was tried for two days and then given up. But surely, as Dr. Spence points out, one can hardly expect the flow of milk during the first two days. There is another idea that seems to me to be erroneous. Mothers are often advised to give up breast-feeding if they have the misfortune to develop a breast abscess. As a rule breast-feeding can be continued from the opposite side, and the milk will return in the damaged breast when it heals. The last sentence in Dr. Spence's paper may surprise some, but it does not surprise me; knowing that paediatrics has always been the Cinderella of medicine, one would have thought that a course of postgraduate teaching in infant feeding and diseases of children would be one of the most important subjects for instruction.—I am, etc.,

Sheffield, Oct. 17.

H. LEADER, M.B.Lond.

SIR,—I recently visited a New England hospital. It was a pleasant place, well equipped and staffed, in a well-to-do town, and largely used by private patients. There was

much evidence of thoroughly kind and unhurried attention to all. I was shown round by the physician in charge of obstetric work, and we reached the maternity wing shortly after noon. The first baby that I saw was in a duty room lying on its back in a crib, with a nurse standing over it and holding a bottle in its mouth. The physician told me, "This little one was born at 5 o'clock this morning." I asked why it was having a bottle. I was told: "It has to have formula, because its mother hasn't any milk yet." We went next to a two-bedded ward where the babies were each 4 days old. Each mother was lying on her back on one side of the bed with her infant on its back on the opposite side of the bed, and each mother was stretching out a hand across the gap between herself and her infant and holding a bottle in its mouth. The conspicuous thing about these babies was that they were entirely "untouched by hand"; a space was maintained between themselves and their mothers, and the babies lay outside the bed covers which were over their mothers. Outside the ward I asked why they were having bottles, and was told: "They have formula when there is deficient breast milk."

By the time we had finished our tour we had seen every baby in the place. Every one was on formula, and every one was receiving its formula in the same detached manner. Not one baby was at the breast. I then asked, "Do any of your patients breast-feed their babies?" and I received a final reply: "We find that very few American women can feed their babies."

I saw two other departments in the maternity wing—the nursery, a large room full of little cradles which were mostly empty but were filling up again now "formula" was over; and the "circumcision room," where I was told that "We strongly encourage every mother to have her baby boy circumcised before she leaves us."—I am, etc.,

London, N.7, Oct. 18.

ANNA R. GLOVER.

SIR,—Dr. J. C. Spence's paper on the modern decline of breast-feeding proved very interesting. There is, however, an apparent fallacy in the figures he quotes from the studies of Grulee and Sanford in Chicago. There is nothing to indicate that the 20,000 babies whom they investigated were equally well fitted from birth to maintain an extra-uterine existence. Let us assume that the vitality of some of these newborn infants is less than it should be. Are these not just the infants who will fail to make progress on breast-feeding, will be perforce put on to artificial feeding, and whose subsequent demise will be attributed not to lack of inherent vitality but to the evil effects of artificial feeding? This lack of vitality may be found in two groups of cases, possibly not entirely unrelated. The first is that group in which sterility, early miscarriage, stillbirth, neonatal death, and death under 12 months of age may be regarded as varying results of the same basal conditions. To appreciate the conditions existing in the second group one must consider the mother and child as one unit. This unit either is or is not having its adequate amount of vitamins, and as a result is either full of vitality, energy, and a tendency to survive, or has none of these desirable features.

It must strike the family doctor quite often that although breast-feeding is the ideal one cannot expect the infant breast-fed by a thin, flat-chested, anxious, overworked mother to flourish according to the expected standards. Can the food from this mother compare with the modern prepared food which is derived from "well-fed contented cows" (as the advertisement has it), living under what are their ideal conditions? In 1929 the North Kensington

Medical Society drew up a report on the infant mortality rate in Kensington as the result of an investigation by a group of practitioners in the area of the available statistics regarding the deaths of infants up to the age of 12 months. The following sentences may be quoted: "If it is accepted that environmental conditions can so affect a mother that an infant at birth is lacking in vitamins, it seems likely that breast milk will be similarly lacking. Could a more unsuitable person be found to breast-feed this particular infant?"

I cannot agree with Dr. Spence's conclusion⁵ that the decline in breast-feeding is due to indifference and to the lack of the doctors' education, since it is a well-known fact (as mentioned in the review of Dr. G. T. Wrench's book *Wheel of Health* in the *Journal* of October 15) "that different individuals show a different susceptibility to dietetic defects, and recently in the laboratory a Mendelian variety of rats has been obtained which succumb to rickets when the vitamin content of the diet is lowered more readily than normal rats. How far can such genetic factors account for differences in physique in different groups of mankind?"

As a general practitioner, I feel I should mention two facts which confirm one's disbelief in the advice usually given to all and sundry as to the desirability of breast-feeding. It is not at all uncommon to encounter cases of rickets in breast-fed babies. It is also a common occurrence for practitioners to find that in the case of an unhappy mother with an obviously unhappy baby the only cause for their many symptoms is that the impossible is being attempted. The change which occurs when the struggle is abandoned, when the baby obtains adequate nourishment and the mother sufficient rest, is dramatic, and the later results of artificial feeding have never in my experience been unsatisfactory. The manufacturers of modern artificial foods are well aware of what is necessary in the make-up of these if they are to produce satisfactory results in practice. I think that the whole position was quite well summed up in one of the findings of the committee of the North Kensington Medical Society: "In suitable cases, where the mother has a natural capacity for breast-feeding and a placid temperament, there is no better method of infant feeding. It seems likely, however, that the environmental conditions under which many mothers attempt to produce breast milk may be as likely to lead to bad results as the somewhat similar conditions which lead to the production of unsuitable cow's milk. Especially is this so if we add the effect of financial and domestic worries to the results of poor feeding, lack of fresh air, and lack of sunlight."—I am, etc.,

London, W.10, Oct. 15.

HORACE A. NATHAN.

SIR,—I would like to thank Dr. J. C. Spence for his excellent article on the decline of breast-feeding (October 8, p. 729). Is it not possible that this decline is in some way connected with the recent rapid rise of municipal child welfare clinics? I run a children's welfare clinic at my house one afternoon a week, and it often happens that I advise a mother to persevere with breast-feeding. Subsequently I have learned that the patient has gone to the clinic and obtained some patent food, usually at a reduced rate. My point is that in my opinion the chief use of these clinics to working-class mothers is merely as a depot for cheap milk. This attitude is definitely encouraged by health visitors, who point this out as an inducement to mothers to attend the clinic; it is probably further encouraged by the staff of the clinics.—I am, etc.,

Carshalton, Oct. 10.

J. SIMON

Infections of the Hand and Fingers

SIR.—I have followed with interest the excellent articles on infections of the hand and fingers (*Journal*, October 1, p. 715; October 8, p. 754; and October 15, p. 798). I feel, however, that the incisions advised by Mr. Norman C. Lake, as illustrated, call for comment. The "ced-mouth" incision for infection of the pulp is not infrequently followed by marked retraction of the pulp flap and leaves an ugly scar, which interferes with delicate touch. The exceptional use of transfixion of the pulp, unless the incisions be more lateral, would certainly interfere with touch on healing.

The incisions over the middle and proximal phalanges should again be more lateral, for two reasons: infection spreads backwards from the front of the finger on to the dorsum, and the incisions as illustrated might not interrupt this spread; also, in highly infected and semi-gangrenous conditions the tissue between the small incisions may break down, resulting in an infected wound across a flexure (deplored by J. B. Murphy). This lack of respect for "flexure rule" is seen in the distal incision for the tendon sheath of the flexor minimi digiti, and the middle one would certainly cut the ulnar nerve. The upper incision of the tendon sheath of the flexor longus pollicis in a swollen condition of the area endangers the median nerve, and a considerable amount of dissection among important structures is necessary to reach the distended sheath. Surely it is better to be guided by Kanavel and approach from the side.—I am, etc.,

Liverpool, Oct. 17.

R. KENNON.

Thimble for the Surgeon

SIR.—Mr. T. E. Coulson has drawn attention in his note in your issue of October 15 (p. 789) to a most valuable technical procedure which should be further known because it seems that many are still unaware of this method, first described by Sir William de Courcy Wheeler in the *Medical Annual* of 1925, and again described by him in the *Journal* of June 6, 1931. This method of cutting down upon the finger protected by a thimble is the most safe and precise way of making a counter-drainage by a stab incision not only in pelvic abscess but in the course of any laparotomy, and a thimble should find its place in every surgeon's kit of instruments.—I am, etc.,

A. DICKSON WRIGHT, M.S., F.R.C.S.

London, W.1, Oct. 18.

"Salt-water Boils"

SIR.—"Salt-water boils" are an affliction of deep-sea fishermen. The condition is so prevalent and so definite that the term "salt-water boils" conveys a very clear clinical picture to any practitioner who has once seen it, and an equally vivid but painful picture to any fisherman who has once suffered from it. The disorder affects only those men directly concerned in the handling of fish on deck; of these the boatswains are most severely affected by reason of their having to stand with upraised forearms beneath the bag of fish preparatory to releasing the catch on to the deck. It does not affect those not concerned with the handling of the fish—that is, engineers, cooks, and skippers.

Two types of lesion occur, one affecting the radial aspects of the wrists, the other the upper parts of the forearms. The lesions on the wrists result from the constant chafing of the

oilskin sleeve on an area saturated with sea-water, which is hypertonic. The skin becomes thickened and a chronic inflammatory reaction, produced by the constant trauma inflicted by the sharp edge of the oilskin, gives rise to a raised, reddened area on which small pustules form from infection of the follicles. The chronic inflammatory process acts as a barrier to the spread of infection, but if a woollen or flannel sleeve is worn as a protection the traumatic inflammatory change does not occur, with the result that the folliculitis which ultimately supervenes is more severe, and comparable with that which occurs on the upper parts of the forearm. During rain-storms the wrists are soaked with a hypotonic solution and the lesion on each wrist is markedly aggravated. The lesion on the upper part of the forearm consists of a severe folliculitis with an acute inflammatory reaction round the central points of infection. The inflammatory areas coalesce, with the production of a swollen and intensely inflamed forearm. The centre of each inflamed area gradually sloughs and discharges after several days.

No other part of the body is affected and there is generally no constitutional disturbance. The lesions are staphylococcal in origin and no immunity is produced. The scars caused by these "salt-water boils" are as occupationally pathognomonic as the blue scars of the collier.

Although the condition is unquestionably occupational, compensation under the Workmen's Compensation Act is refused (at least in this port) on the grounds that: (1) there is no antecedent history of injury; (2) the lesions are "boils" and therefore outside the Act: the prefix "salt-water" is ignored, as is the significance of its widespread use throughout the British Isles; (3) the condition is not one of "sepsis." The most successful prophylactic I have used so far is acriflavine emulsion (*B.P.C.*). The emulsion is rubbed into the forearms before going on watch; the forearms are washed well with soap and water after coming off watch, and a little of the emulsion is again rubbed in. Many theoretical methods of prevention fail because they are too complicated for tired men to bother with, or are hopelessly impracticable under sea conditions. I would be grateful if practitioners in other fishing ports who see this condition would give me the benefit of their experience, particularly with regard to the questions of compensation and of prophylaxis.—I am, etc.,

Milford Haven, Oct. 17.

W. BURNETT EVANS.

The Treatment of G.P.I.

SIR.—In your annotation on the report on malarial therapy in the *Journal* of October 15 (p. 796) it is mentioned that of between five and seven hundred cases of general paralysis yearly since 1927 about 15 per cent. are said to have been discharged "cured." I presume by the word "cured" is meant a full remission, as the subsequent history of these cases cannot yet be fully ascertained. You also state that "the report does not concern itself with the mechanism of the therapeutic action or with any comparison with other methods of inducing pyrexia." Kraepelin's compilation of 3,079 cases treated with malaria showed a death rate of between 10 and 30 per cent. due to the malaria and a remission rate of about 20 per cent., while of Neymann's collection of 979 cases treated by electropyræxia 27 per cent. showed a full remission with a death rate as a result of the treatment of only 2 per cent.

Surely in view of the extreme seriousness of infecting patients with malaria who are already suffering from serious disease of the central nervous system an authoritative comparison with other methods of treatment is long overdue.—I am, etc.,

St. Mawes, Cornwall, Oct. 17.

B. H. SHAW, M.D.

"Giving up Smoking"

SIR.—The abandonment of tobacco is often indicated on medical grounds, but individual patients differ in their reaction to this deprivation. Some people find the sacrifice a trifling matter, and in most cases the sense of loss vanishes in a few weeks. There remains, however, a certain class to whom the surrender of their accustomed "normalizer" is a real and prolonged ordeal, and in these cases a medical man may be asked for some means of mitigating the distress entailed by the prohibition of tobacco.

In the course of my work on drug addiction I observed that persons who were undergoing the form of belladonna medication associated with my name often lost all desire for tobacco as treatment progressed. I had not intended to produce this result, for, when a dangerous drug has been given up, the minor indulgence of tobacco is beneficial rather than otherwise. Six months ago, however, a number of such patients were invited to co-operate in a simple experiment—namely, that of deliberately refusing the unwanted cigarette and only smoking when they really felt the need. When the mechanical part of the habit was thus diminished by a trifling exercise of will, the need for tobacco soon ceased. More recently several inveterate smokers who had failed to cure the habit for themselves underwent a simplified form of treatment with good results.

If any particular patient knows that the abrupt stoppage of tobacco will be a formidable undertaking, he will have to consider whether it is worth his while to set aside a week for adequate treatment. He will need to keep very quiet over this period, and for the last few days to be more or less confined to bed, for only when rest is fairly complete can a satisfactory result be expected. Minute doses of drugs of the belladonna group (for example, atropine grain 1/1,000 rising to 1/500, orally) are administered every two hours, in such a way that, while the heart-beat is appreciably retarded, no physiological symptoms are observed by the patient. Dryness of mouth and ocular symptoms signify that the dose is too large and must be reduced. On his part the patient must promise never to smoke unless he definitely feels the appetite for it, and must throw away the cigarette that he is not enjoying.

The process is simple, but if the doctor sees his patient once a day to be sure that vagal preponderance (as shown by a slowing of the heart-beat while at rest) is being constantly produced, he will find that tobacco becomes progressively less attractive and finally ceases to be desired. —I am, etc.,

London, W 1, Oct. 18.

G. LAUGHTON SCOTT.

Adult Scurvy

SIR.—I was interested in the paper by Dr. G. H. Jennings and Surgeon Lieutenant A. J. Glazebrook on this subject in the *Journal* of October 15 (p. 784). For every case showing a full clinical picture of the disease one must encounter many persons suffering from subclinical states of the same condition. Happily, a moment's inquiry into the patient's diet will indicate whether further investigation is worth while.

May I instance the case of a man of 29 whom I saw recently, complaining of petechial spots on the legs, "blood blisters" in the mouth, and a sore tongue. He had had two previous severe attacks of the same spots, diagnosed as "purpura," while serving in the Indian Army, during which period he had developed foul, bleeding, spongy gums, necessitating removal of all his teeth. At

that time he had taken no fruit for some months. Since residing in this country he had noticed two years ago one crop of petechiae on the shins which persisted for a few days. Apart from slight fatigue at the end of his day's round as postman, he had had no further symptoms until the onset of his present oral and skin haemorrhages. He did not care for fruit, and although he occasionally took a fresh vegetable salad with his meals he had, in fact, had no fruit for the past month. Examination revealed a healthy-looking man with petechiae on the legs only up to the line of the garters, though petechiae also appeared on the arms a day or two later. The liver and spleen were not palpable; the blood pressure was 140/82 mm. Hg. No abnormal physical signs were detected in the lungs or heart; the urine contained no blood.

The patient's garters had performed a ready-made capillary fragility test, and a modified Harris and Ray test showed a deficiency of just over 900 mg. of ascorbic acid. No further petechiae appeared after saturation with ascorbic acid, and with regulation of his diet the patient has since been well and has lost his fatigue.—I am, etc.,

Essex, Oct. 19.

R. N. C. SMITH.

SIR.—It is surprising to read that Dr. G. H. Jennings and Dr. A. J. Glazebrook find adult scurvy to be a rare condition. In this city at least it is quite often seen, and the diagnosis can readily be made on clinical grounds if the possibility of its occurrence is borne in mind. The following are brief accounts of the thirteen cases seen at this hospital during 1937:

Case 1.—Male, aged 73; single; admitted June 6, 1937. Haemarthrosis right knee, for one month; purpura right arm; gums normal, no teeth. Deficient diet, little fruit.

Case 2.—Male, aged 74; single; admitted June 21, 1937. Swelling of legs for three weeks; purpuric haemorrhages both thighs. Teeth loose and septic; soft gums. "Not eaten much for some time."

Case 3.—Male, aged 76; widower; admitted June 29, 1937. Three weeks' ecchymosis right ankle and left knee; soft bleeding gums. Eats no fruit and very little vegetable.

Case 4.—Male, aged 42; single; admitted July 3, 1937. "Pyorrhoea six months"; bleeding gums; foetor oris marked. Petechiae on legs, ecchymoses on both feet.

Case 5.—Male, aged 70; single; admitted July 5, 1937. Anorexia; spongy bleeding gums; purpuric eruptions on both feet.

Case 6.—Male, aged 64; married; admitted July 26, 1937. Large ecchymoses over whole of left leg for four weeks. Bleeding gums; complete anorexia; hypochromic anaemia.

Case 7.—Male, aged 62; single; admitted July 31, 1937. Ecchymosis both thighs and legs, also left arm; spongy gums. Does not eat any fruit.

Case 8.—Male, aged 51; married; admitted August 9, 1937. Ecchymosis of legs for one month; many petechiae; soft gums; does not eat any fruit or vegetables.

Case 9.—Male, aged 63; widower; admitted August 9, 1937. Purpuric haemorrhages both legs; dyspnoea; angina. Edentulous; gums normal.

Case 10.—Male, aged 77; widower; admitted August 9, 1937. Large ecchymosis of left leg for one month; bleeding gums. Cannot remember when he last ate fruit or vegetables.

Case 11.—Male, aged 56; separated from wife; admitted August 30, 1937. Large ecchymosis on right leg and foot for four months; bleeding gums; no fruit or vegetables for six months.

Case 12.—Male, aged 62; single; admitted October 13, 1937. Haemarthrosis of the knee for one week; many petechiae; ecchymoses both ankles. Edentulous; gums normal. Does not eat fruit.

Case 13.—Male, aged 60; widower; admitted October 17, 1937. Purpuric eruption and ecchymoses on both legs.

marked hypochromic anaemia. Edentulous; gums normal. "Unable to look after himself."

All these patients made complete recoveries on being given large amounts of orange juice, and extensive laboratory investigations were not considered necessary. The following points may be worth noting:

1. The patients are men past middle age who in most cases have no womenfolk to look after them.
2. A history of a vitamin-C-deficient diet can nearly always be obtained.
3. Haemorrhages in the legs, either ecchymoses, purpuric haemorrhages, petechiae, or haemarthroses, are a constant finding.
4. Bleeding, spongy gums are usual, but in the absence of teeth the gums are normal.
5. Anaemia, usually hypochromic, is common.
6. The condition rapidly clears up on giving orange, lemon, or tomato juice.

A further interesting point is that the great majority of patients first come to hospital in the spring and summer months. In 1936 eight cases were admitted: one in January, two each in June and July, and three in August. In 1937 there were three cases in June, four each in July and August, and two in October. So far this year we have had sixteen cases: one in February, one in March, three each in April and May, four in June, one in July, and three in August. Drs. Jennings and Glazebrook's cases first came to hospital in July and in August. The likely reason for this seasonal incidence is that the price of oranges in April and May is about double the average price during the rest of the year.

I have to thank Dr. H. H. MacWilliam, medical superintendent of the Walton Hospital, for permission to record these cases.

—I am, etc.,

Walton Hospital, Liverpool, Oct. 19.

A. MARTINEZ.

Sulphanilamide for Filarial Lymphangitis

SIR,—For the past few months I have been using sulphanilamide in cases of filarial lymphangitis due to the *Filaria bancrofti*. The treatment of this disease has always been very unsatisfactory, and in some tropical countries, such as Fiji, the condition is very prevalent and causes many tropical residents lifetime misery and ill-health, often with repulsive deformity.

A typical case was that of a man aged 51, an outdoor worker of regular habits. Since the age of 8 he had been the subject of attacks of filarial lymphangitis. The attacks lasted a week and often occurred every month—rarely was the interval between attacks as long as three months. Of late years his left leg had permanently increased in size (elephantiasis). In a typical attack he would be seized with chills and fever, with anorexia and sometimes vomiting. The left leg would become red, swollen, and very painful, and the lymphatic glands of the left groin would enlarge, becoming painful to the touch and requiring hot fomentations to relieve the pain. The lymphatics would become red and inflamed and visible from knee to groin. These attacks would last about a week.

On the other hand, a typical attack treated with sulphanilamide was as follows: on September 21 his temperature was 102° F., the left leg was red, and the patient suffered from chills and was confined to bed. At 6 p.m. he began taking prosectasine, 7½ grains every four hours. On September 22 at 8 a.m. the temperature was normal; the redness of the left leg had disappeared; there was no pain in the groin from adenitis; and he had a good appetite and was able to walk about. On September 23, after taking altogether eight tablets, he was quite well again.

This shows that sulphanilamide has a direct and rapid therapeutic action in the treatment of filarial lymphangitis, and further investigation should be made of its possibilities in this disease.—I am, etc.,

Fiji, Sept. 23.

A. E. BOTSFORD DENOVAN.

The Occipito-posterior Case

SIR,—At the present time there is much thought and discussion regarding the various means by which the standard of obstetrics, as commonly practised, may be raised. It is generally agreed that the education of the medical student is of prime importance in this respect.

With all due regard for the experience of Dr. David Price (*Journal*, September 17, p. 638), I feel that his views are hardly suitable as advice to the student or young practitioner. When using forceps he violates two cardinal principles in that he does not wait for full dilatation of the cervix, nor does he first make an accurate diagnosis of the position of the foetal head.

As resident in various maternity hospitals I have seen several cases sent in as "failed forceps." In five of these the failure was due entirely to disregard of the above rules, not to any other obstetric abnormality. From these cases and others I have gained the impression that many practitioners will attempt any forceps delivery without hesitation, whereas, when confronted with other abnormalities, they realize their limitations and arrange for consultation or removal of the patient to hospital. I would put forth a plea, therefore, for more intensive education of the undergraduate student in the proper understanding and use of the obstetric forceps.—I am, etc.,

St. Michael's Hospital, Toronto,

B. E. MEEK.

Identical Cancers in Identical Twins

SIR,—Your annotation on this subject (October 8, p. 753) contains a statement which should be contradicted. Surely it is untrue to say that "usually, if a cancer develops in one of a pair of identical twins, the other twin has a cancer of the same type in the corresponding organ, either at the same time or soon afterwards." The exact percentage of cases in which concordant cancers develop will be known, at any rate for Germany, when the data now being submitted to the Kaiser Wilhelm Institute for Anthropology in Berlin are finally analysed. In the meantime Versluys (1934) and Weitz (1936) have adduced evidence that concordant cancer in identical twins is exceptional. Error arises because, as German workers have repeatedly pointed out, twin statistics compiled from random cases in the literature are worthless. Luxemburger (1932), for instance, collecting twins with schizophrenia from the literature, found 82 per cent. concordant. Submitting a questionnaire to the superintendents of various mental hospitals, he found 56 per cent. concordant; but when he took the trouble to compile a personal series, finding out from the registries which schizophrenic patients were twins, the percentage of concordance dropped to less than 20.

The likelihood of an identical twin developing cancer when the other member of the pair already has it is quite a practical problem, because several hundred such cases occur every year; they are often distressing, and the practitioner responsible needs guidance. But the theoretical side of the question is even more interesting. Roughly, there are three different types of reaction between heredity and environment. In the first group come diseases like haemophilia, which are more or less independent of the

environment: it is characteristic of these cases that they are uncommon, that identical twins always agree provided they live long enough, and that there is, theoretically, a simple mathematical relation between the proportion of non-identical twins which develop the disease concordantly and the proportion which do not. In the second group come diseases, such as disseminated sclerosis, where heredity is completely unimportant and identical twins show no tendency to concordance at all (Thums, 1936). The third group lies midway between these extremes, and includes the majority of common diseases. In this group heredity and environment are both important, the explanation being that if a disease is due to a single predominatingly important environmental factor such as vitamin D shortage or a badly balanced mineral content of the diet, different individuals will vary in their sensitiveness to the harmful factor, and, providing that the deficiency acts fairly evenly on a population, hereditary variations in sensitiveness will determine which individuals are affected and which escape.

Twin material and certain family pedigrees and animal breeding experiments leave little doubt that some cases of cancer fall into the first group of "inevitable" disease. But if allowance is made for the existence of these cancers there is little evidence that heredity plays much part in the general incidence of cancer. That is a depressing conclusion to reach, because if cancer were due to a few simple carcinogenic factors in our environment we should presumably, like the laboratory mouse (Bonser, 1938, and others), show hereditary variations in susceptibility, and heredity would then be as important in cancer as it is in rickets (Lehmann, 1934). In other words, cancer is theoretically an unpromising problem in preventive medicine.—I am, etc.,

Oxford, Oct. 18.

Sarcoidosis of Boeck

SIR.—It is to be hoped that Dr. R. Bodley Scott's article on the sarcoidosis of Boeck (*Journal*, October 15, p. 777) will succeed in making more widely known a systemic disease first described many years ago by dermatologists (Besnier, Tenneson, Boeck). Besnier (1889) believed it to be caused by the tubercle bacillus, his patient showing "*le plus remarquable exemple de synovite fongueuse symétrique que l'on puisse observer*." Boeck suggested in his first paper (1899) that "perhaps, later on, they may be found to represent benign forms of so-called pseudo-leukaemic affections of the skin." It was, however, only in 1915 that the first comprehensive report appeared other than in the dermatological literature. It was written jointly by a dermatologist and a physician on seven cases showing the typical lesions in skin, lungs, and partly also in spleen, kidney, and mucous membranes (Kuznitzky and Bittorf). Although in the following years Jüngling's papers (1920, 1928) did much to make the osseous lesions familiar to radiologists and (from 1920 onwards) several cases were reported in ophthalmological journals, it still remains true that "the disease is not even mentioned in the textbooks of internal medicine" (Salvesen, 1935). Schaumann's important contributions (since 1914) also had long remained unnoticed except by dermatologists, and it is only recently that in

more generally accessible journals authoritative articles have been published in which more attention is given to the natural history of the disease and the involvement of internal organs than to its puzzling aetiology (Denmark: Kissmeyer, 1932. Austria: Bergel and Scharff, 1933. France: Pautrier, 1935; Rist, 1937. Sweden: Salvesen, 1935, United States: Longcope and Pierson, 1937. Switzerland: Loeffler, 1937. Holland: Snapper and Pompen, 1938. This list includes only monographs and the first of the more important papers published in these countries).

It is not difficult to add from the recent literature to the case mentioned by Dr. Scott other cases reported as of chronic miliary tuberculosis or tuberculous splenomegaly in which the diagnosis of sarcoidosis would appear to be more probable. In their excellent monograph on chronic miliary tuberculosis Hoyle and Vaizey (1937) have presented a number of cases of sarcoidosis as examples of chronic miliary tuberculosis, although they expressly discuss sarcoidosis in the chapter on differential diagnosis. The tendency to include such cases into the entity of chronic miliary tuberculosis seems to be traceable to the influence of four publications which dealt most exhaustively with the pathology of the condition from a morphological point of view but which seem to have somewhat obscured the actual clinical picture (v. Hansemann, 1915; v. Gebattel, 1920; Askanazy, 1921; Mylius and Schürmann, 1929-30).

A correct diagnosis is of importance with regard to both prognosis and treatment. Some of those cases which later developed pulmonary tuberculosis may have become infected while being treated for the lesions of sarcoidosis in a sanatorium. I myself know of a patient who died from splenectomy; a fuller appreciation of the significance of the symptoms—generalized glandular enlargement (biopsy: numerous tuberculous cell systems); splenomegaly, and partial facial paresis of some years' standing—could have avoided this issue. Another case with splenomegaly as leading symptom has been reported by Dressler (1938), which has the additional interest that the diagnosis was established by sternal puncture; the patient had refused to permit dissection of a lymph gland or puncture of the spleen.

In recent radiological literature a number of cases of atypical tuberculous bone lesions have been reported in which the diagnosis of sarcoidosis or of osteitis tuberculosa multiplex cystoides has been erroneously made (Van Alstyne and Gowen, 1933; Vastine and Bacon, 1935; Connolly, 1938; Thornton, 1938). It seems no longer justified to retain for one of the signs of sarcoidosis a term which is most probably misleading with regard to the aetiology. While some of these cases would seem to belong to the syndrome of "tuberculous cysts and abscesses of epiphyseal lines," described by Kienböck (1930), a recent paper by Buttinger (1938) gives a good example of unusual "cystoid" bone tuberculosis, which the author properly refrains from classifying under one of the known syndromes.

It would appear that the question of the cause of sarcoidosis will have to be adjourned at least until more (positive or negative) facts are known regarding ultra-microscopical or other forms of the tubercle bacillus. Twenty years ago the finding of Much's granules in sarcoid lesions was reported by several authors, but nobody seems now to attach any significance to these granules. The various findings and hypotheses offered by some authorities as proof of a tuberculous aetiology have recently been presented again by Pinner (1938). No new facts are added by this author, and he does not mention

the many objections brought forward against these hypotheses. Danbolt and Brandt (1938) have described a case of sarcoid-like cutaneous tuberculosis caused by the avian tubercle bacillus, but they do not regard this case as one of the sarcoidosis of Boeck, "as this disease is in our opinion scarcely ever caused by tuberculosis." That "there is no convincing evidence that sarcoidosis is a manifestation of tuberculosis" (Scott, 1938) seems to be the only possible critical attitude to-day.—I am, etc.,

London, S.W.2, Oct. 22.

Ether Convulsions

SIR,—It appears to me that both carbon dioxide lack and carbon dioxide excess may play their part in the causation of "ether convulsions." It is, of course, true, as Dr. Nosworthy has heroically demonstrated, that gross excess of carbon dioxide in the inspired air will eventually produce convulsions. On the other hand, there is considerable clinical evidence to support the carbon-dioxide-lack hypothesis; for example:

1. Many cases of "ether convulsions" were reported during pure insufflation endotracheal anaesthesia without rebreathing, under which conditions the alveolar carbon dioxide concentration is abnormally low.
2. "Ether convulsions" have many times been stopped by the addition of carbon dioxide to the inspired air.
3. Examination of the urine first passed after an attack has shown a high alkalinity, so that the patient was presumably suffering from alkalosis.

There is no doubt that the subject is a most complex one, and that in the present state of our knowledge we are not competent to explain the mechanism of the causation of this interesting condition.—I am, etc.,

London, N.W.8, Oct. 21.

C. LANGTON HEWER.

Adrenaline Treatment of Asthma

SIR,—May I stress two rather unpleasant sequelae of the treatment of asthmatic attacks by adrenaline. First, the employment of adrenaline during a cold in the head, with the patient up and about, is not seldom followed

by a very rapid spread of infection to the lower bronchial tract. As attacks of asthma are often more persistent during such infections a larger dosage may be resorted to just at these times. Secondly, in cases in which the dose has been gradually increased up to, say, $\frac{1}{4}$ c.cm. every two or three hours the condition may pass into one of continuous dyspnoea and cyanosis, which is unrelieved by adrenaline alone.

It would be interesting to discover the exact cause of this condition and also the frequency of its occurrence in private practice. Can adrenaline in a toxic dosage produce active pulmonary congestion? Are the symptoms those of early cardiac failure due to repeated overstimulation? Finally, are there patients with whom adrenaline is a true drug of addiction, in the sense of antibody production, and in whom the "anti-hormone" is the real toxic factor?—I am, etc.,

Queen Mary's Hospital, Carshalton,
Surrey, Oct. 22.

JOAH BATES.

Medical Re-education

SIR,—In your recent Educational Number (September 3) there was a constructive article of remarkable frankness and clear analysis by Sir Walter Langdon-Brown. His information regarding the proceedings of two committees on the medical curriculum was both illuminating and suggestive—illuminating the cause of the relative confusion of opinion regarding the curriculum and suggestive of the beginning of an answer. It seemed as if human wisdom had failed, to devise a scheme to which all would subscribe for the training of the men who are to be stewards of the nation's health. The survival value of the Empire itself depends on the integrity of its health, if the word is given its most universal connotation.

In our approach to the subject we need a more fundamental conception of the nature of the problems. Sir Walter's article begins with the student at his entry into the medical school. But already the student (I speak from my own fairly recent experience) has many unsolved personal problems. Now the curriculum makes no provision for dealing with these, and he may finish his course no better equipped in this respect than he was at his entry. In point of fact he has generally added other unsolved problems to his psychological make-up. This is unsatisfactory, for we know that in practice we see patients every day whose illness is influenced, or even caused by, those same fears (as Sir Walter noted), family problems, and other emotional compromises to which the practitioner himself is exposed and for which he may have no answer. An example. Every psychologist of the eclectic school at least, and most general practitioners, will agree that the deepest and commonest problem is security, which gives rise to fear when it is threatened. It may be economic or affectional security that is threatened. He is afraid lest he will not have enough, or because someone does (or did) not love him enough. The security problem is common in our profession. We all know what it means. We have often put our security in our reputation—our reputation in the eyes of the very people who come to us for help. But we cannot release them if we are not free ourselves.

Another problem was quoted by Sir Walter Langdon-Brown, and more recently in another reference by Lord Dawson of Penn in his address at the opening of the new medical school at Aberdeen University. He described how, taking the country as a whole, there had been a gradual growth of medical services and hospitals which,

however individually excellent, had become a medley of separate efforts. This same lack of unity, arising from insistence on a point of view, was expressed in Sir Walter's committees, where everyone agreed on the necessity for pruning the curriculum—at the expense of the other fellow's subject!

The answer seems to consist in attaining a new level of thinking and acting by a change in human nature itself. This is the forgotten factor in medical education. The physician must be healed himself. Or his teachers must see that the medical student is equipped in this respect before he is entrusted with the care of people who are similarly sick. The magnitude of the task is great, involving as it does every member of the profession and every student. But the effort would usher in the next great advance in therapy and research. It would enhance the value of the medical service to the community.

The expression "moral rearmament" has recently been the subject of Press articles and correspondence in the *Times*. It seems to me that this approach to the subject of medical education is part of the moral rearmament that our profession needs, and by which an immense contribution can be given to bringing about a settled state of the world.—I am, etc.,

The Services

NAVAL COMPASSIONATE FUND

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on October 14, Surgeon Vice-Admiral P. T. Nicholls, C.B., K.H.P., Medical Director-General of the Navy, in the chair, the sum of £164 was distributed among the several applicants.

DEATHS IN THE SERVICES

Lieutenant-Colonel ARTHUR ROWLAND GREENWOOD, R.A.M.C. (ret.), died at Bexhill-on-Sea on October 11, aged 64. He was born on January 19, 1874, was educated at Middlesex Hospital, and, after taking the M.R.C.S.Eng. and L.R.C.P. Lond. in 1897, entered the Royal Army Medical Corps as lieutenant on June 21, 1900. He became lieutenant-colonel on January 26, 1917, and retired on June 26, 1924. He served in the war of 1914-18, and was mentioned in dispatches in the *London Gazette* of February 17, 1915. He had been a member of the British Medical Association for twenty-one years.

Captain JOHN JOSEPH CEDRIC RAINSBURY, R.A.M.C., died on August 13. He was educated at Sheffield University, where he graduated M.B., Ch.B. in 1932. After filling the posts of house-surgeon at the Jessop Hospital for Women and of house-surgeon and ophthalmic house-surgeon at Sheffield Royal Hospital he entered the Royal Army Medical Corps on January 1, 1935, and had recently been placed on temporary half-pay on account of ill-health.

Obituary

L. S. DUDGEON, C.M.G., C.B.E., F.R.C.P.

Professor of Pathology, University of London; Director of Pathology and Bacteriology, St. Thomas's Hospital

St. Thomas's Hospital, the Medical School, and the whole cause of medical education have sustained a crushing blow in the death on October 22, after a few days' illness, of Leonard Stanley Dudgeon; he himself would have scorned the suggestion that anyone was irreplaceable, but in this period of transition which vitally affects the voluntary hospital system and the changing shape of medical education the loss is irreparable.

Dudgeon joined St. Thomas's in 1894; in 1899-1900 he was assistant house-physician and house-physician; he obtained the Membership of the Royal College of Physicians in 1901 and was elected Fellow in 1908. Soon after qualification he became associated with Louis Jenner and was greatly influenced by Professor Shattock—association and influence which led him to become one of the early workers in bacteriology and pathology as specialized subjects. All through his career he set for himself an exceptionally high standard; he quoted Professor Shattock as one who served pathology well in preventing acceptance as fact of work which was non-proven; Dudgeon did not publish the results of his research work until, in his own mind, he was satisfied that his findings were sound and founded on fact. An astoundingly accurate memory was one of his great assets: his opinion and reasoned advice on any subject connected with the hospital were ever at the disposal of his colleagues; his sound judgment made him an invaluable committeeman.

As Dean of the Medical School Dudgeon attended to every detail, and held the full confidence of the staff and lay body. During his deanship the Anatomy Department has been rebuilt; the Library, the Department of Chemistry, and the Sherrington School of Physiology have been largely transformed; and thanks to the generosity of his friends, Mr. Michael and Sir Sidney Herbert, an Institute of Research has been built on the roof of the Medical School. He was an excellent teacher: he enjoyed teaching, and instilled his own enthusiasm into those he taught. A good tactician, he was an exponent of "letting the other fellow talk"; he had the gift of so organizing his time that he found—made—time for everything, and was a supreme example of a favourite adage, "It is only the busy man who has time for everything." Whatever other calls were made upon him, he invariably placed first his engagements in the hospital and medical school, and however inconvenient the time or distance he was always at the disposal of his colleagues and friends who needed his help, personal or professional. His academic distinctions included the Croonian, Horace Dobell, and Erasmus Wilson Lectureships, but his bent was more practical than academic.

In 1903 Dudgeon was appointed Superintendent of the Clinical Laboratory of St. Thomas's Hospital; in 1905

Director of Pathological Laboratories and Bacteriologist; in 1927 Curator of the Shattock Museum. He held a University of London Professorship in Pathology. In 1915 he put aside his appointments and practice and served with great distinction as Colonel A.M.S., Consulting Bacteriologist in Salonika and the Eastern Mediterranean. He was mentioned in dispatches three times, and was awarded the C.M.G. and C.B.E. At the Special Clinical and Scientific Meeting held by the British Medical Association in April, 1919, to discuss problems arising out of the war, he read the opening paper on "The Dysenteries: Bacillary and Amoebic." In 1928 he succeeded Sir Cuthbert Wallace as Dean of the Medical School of St. Thomas's, and for the last ten years played a most important part in the organization and administration of the Voluntary Hospitals Committee: he was chairman of the Deans Committee, a member of the Senate of the University of London, and was a leading figure in early teaching co-operation between the medical schools and the L.C.C. hospitals, rendering great service during the stage of re-adjustment through which the voluntary hospitals and medical schools are passing.

Dudgeon not only studied under Shattock, he studied Shattock, and, as part of the pathologist's outfit, assumed the somewhat brusque mannerisms of the shy, lonely man who was Shattock. Brusqueness was no natural characteristic of Dudgeon; he was a man brimful of humanity and innate kindness, though such a description of himself would have annoyed him intensely. He suffered not gladly those whom he regarded as fools, but he had high ideals of justice, and some of his kindest actions, known only to those who were in his confidence, benefited people whom he had little cause to like but for whom he was sorry. A devoted family man, he had great zest in life; he enjoyed dining out, the company of his fellow-men; and he took a lively interest in outdoor games. He was a contented golfer, a former captain of Beaconsfield Golf Club, and he seldom missed a big match at Twickenham or notable athletic meetings. He was the staunchest of friends to those whom he regarded as friends; he had extraordinarily high ideals in his devotion to his work and whatever he took in hand: he holds high place indeed among those who, during the eight hundred years of the hospital's history, have given the best of their lives to St. Thomas's.

R. J. C. T.

By the death on August 29 last, at the age of 89, of CHARLES WALTER EVANS, at his residence, Matlock House, Bakewell, Derbyshire loses its oldest medical practitioner and the profession another of the old school of respected family physicians. A full obituary notice appeared in the *High Peak News* of September 3, 1938, which set out his local interests and activities over many years. He was born on January 19, 1849, at Winstar, and was the eldest son of Charles Evans, F.R.C.S.Eng., who practised there, the family being a very old Derbyshire family, and also connected with Florence Nightingale. At the age of 3 he went to Bakewell with his father, who had purchased a practice there. He was educated at Derby Grammar School, where he obtained a first class in the London matriculation examination, afterwards studying at University College, London, where he obtained his L.S.A. and M.R.C.S.Eng. in 1876 and M.B.Lond. in 1878. He was apprenticed to Dr. Lomas of Belper before qualification, as was the old custom. Subsequently he held the appointments of house-surgeon to the South London Eye Hospital, the Shrewsbury Eye, Ear, and Throat Hospital, the Warneford Hospital, Leamington, and Gloucester Infirmary. He was assistant medical officer to the Kent County Lunatic Asylum and Three Counties Asylum, Bedfordshire. For a time he was acting medical officer, North-West District

of Chelsea and No. 5 District of London. He was also acting medical officer and public vaccinator, Martley Union, Upton-on-Severn, Worcestershire, and visiting surgeon to the Hospital for Sick Children, Cheltenham. Dr. Evans finally settled down at Bakewell in 1886 on the death of his father, and succeeded him as medical officer of the Bakewell Union Infirmary, a post he held for forty-two years, retiring in 1928, when his son was appointed. He was M.O.H. to the Bakewell Urban District Council for over forty years, held the posts of certifying factory surgeon and school medical officer, and was physician to the Bakewell Dispensary for a long time. He was interested in the foundation of the Bakewell War Memorial Cottage Hospital, and was on the original committee. He had been a member of the Derbyshire Panel Committee for many years, and joined the British Medical Association as long ago as 1877. He had been in failing health during his latter years. He married in 1896 Cornelia Florence Handley Lawton of Manchester, who predeceased him, and is survived by his three sons and two daughters.

We regret to announce the death on September 28 of Dr. ERNEST BONNEY of Kensington, third son of the late Dr. W. A. Bonney of Chelsea. Dr. Bonney was born in 1875, and received his medical education at Charing Cross Hospital. He did brilliantly in the school, taking a number of prizes, and he subsequently held the posts of house-surgeon and house-physician. After a period as house-physician at the Victoria Hospital for Children, Dr. Bonney was appointed resident medical officer at the Kensington Children's Hospital, a post he retained for a number of years, during which time he acquired a considerable knowledge of children's diseases. He became so popular in the neighbourhood that when he retired to take up general practice a public presentation was made to him. Dr. Bonney possessed great ability and was extremely conscientious in his work, never sparing himself in his efforts to do the best for his patients; indeed, he may be said to have worn himself out in their service. He was a man of very varied activities and knowledge, exceedingly well read, especially in matters relating to history, art, and music, and a good singer, a gift which he inherited from his father. He was young both in body and spirit, and the profession is the poorer for his passing. He leaves behind him a widow and a son and a daughter, the former of whom is following his father's steps in the medical profession.

Mr. FRANCIS CHARLES ABBOTT, who died in London on October 6, had lived for some years at The Hermitage, Bletchingley, Surrey. He was born in 1867 the second son of the Rev. R. A. Abbott, and after schooldays at Bruce Castle entered St. Thomas's Hospital, where he won the Cheselden medal and treasurer's gold medal and a university exhibition and gold medal in anatomy and organic chemistry. After taking the M.R.C.S. and L.R.C.P. diplomas in 1888 he graduated M.B.Lond., with gold medal in obstetric medicine, and B.S. in 1890; and at the M.S. examination three years later he qualified for gold medal, having already become F.R.C.S.Eng. He was appointed assistant surgeon, aural surgeon, and lecturer on practical and operative surgery at St. Thomas's, and surgeon to the Evelina Hospital for Sick Children. During the Greco-Turkish War of 1897 Mr. Abbott served as chief medical officer to the National Fund for the Greek wounded, and received a decoration. For his war work in 1914-18, as surgeon-in-charge of Red Gables Hospital, he was awarded the C.B.E. He had been vice-president of the Chelsea Clinical Society and belonged to the British Medical Association for fifty years.

Dr. JOHN WILFRED BIRD, D.S.O., who died at Egham, Surrey, on October 17, aged 66, was a student at Guy's Hospital and qualified M.R.C.S., L.R.C.P. in 1896. After serving as house-surgeon at the Hull Royal Infirmary and clinical assistant at the Royal London Ophthalmic Hospital and the Central London Ophthalmic Hospital, he entered

the Royal Navy, retiring at the end of eight years. He then took up general practice, and became medical officer to the Egham Cottage Hospital and the Windsor Union Infirmary, and police surgeon for the Egham Division. In 1914 he volunteered for foreign service, and held the posts of officer commanding the 2/6 London Field Ambulance and 71st General Hospital, with the rank of lieutenant-colonel R.A.M.C.T. He was mentioned in dispatches for his services in France, Macedonia, Egypt, and Palestine, and received the D.S.O. After the war Dr. Bird was a member of the Egham Urban District Council for eleven years and chairman for three. He had been a member of the Guildford Division of the British Medical Association since 1921.

The death has occurred at the French army hospital, Val-de-Grâce, after a short illness, of Surgeon General MAURICE CARAYON at the age of 57. His administrative gifts secured his rapid promotion during the great war, when he was attached to headquarters. In March, 1936, he was appointed surgeon general, and since then he had been in charge of the army medical service in the Amiens area.

Professor O. CROUZON, who died recently, was born in Paris in 1874, and was the first to be appointed to the new chair of medico-social aid at the University of Paris. He did much to raise the standard of nursing in France, and contributed important studies on neurological and psychiatric subjects.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

Rather unexpectedly the incidence of acute poliomyelitis has risen in England and Wales in the course of the last two weeks. Being a disease of hot climates, and in all countries most common during the hot months, a reduction in the incidence was confidently expected to accompany the fall of air temperature observed at the approach of winter. Of the 77 (65) cases notified in England and Wales, 12 (2) were in Oxfordshire, 11 (9) in Essex, and 7 (1) in Leicestershire. Last week the three counties chiefly affected were Essex, Carmarthen, and Lancashire. Other areas affected to a less degree were: Sussex East, 6 (3), 4 each in Carmarthen (6), Glamorgan (2), and London (6)—Fulham, Hackney, Shoreditch, Camberwell—and 3 each in Chester (2), Gloucestershire (0), Lincoln (2), Southampton (2). More than one case was reported from the following centres: Oxford 11, Leicester 7, Harwich 7, Cuckfield 6, 3 each in Stamford and Tendring, 3 each in Chester, Bristol, Middlesbrough, Cardiff, Llanelly Rural, Between July 17 and October 8, when the seasonal increase was first noticed, 806 cases were recorded for England and Wales; of these 135 cases occurred in Essex, 60 in London, 64 in Yorkshire, 54 in Lincoln, 48 in Sussex, and 34 at Swansea. Of the 6 cases notified in Scotland, 2 were in Dunfermline, 1 each in Glasgow, Inverness Borough, Inverness County, and Kirkcaldy.

In Germany during the week ended October 1, cases declined from 375 to 337—the chief centres affected were the following. Cologne district 28 (44), Bavaria 54, Wiesbaden 26, Dusseldorf 21, Württemberg 54, Saxony 27, Hessen 19, Austria 26. In Holland 32 (44) cases were reported during the week ended October 8, 12 (18) of which occurred in the Province of South Holland.

Enteric Fever

During the week under review there was an increase in the incidence of enteric fever in England and Wales—32 (24) in which London shared—11 (5). Two-thirds of the cases occurred in the counties of Lancashire and London. In Lancashire there were 10 (2) cases, distributed thus: Eccles 4 and 1 each in Crosby, Manchester, Bolton, Urmston,

Wardle, and Ashton-in-Makerfield: in London the 11 cases were in Kensington 3, Woolwich 3, Westminster 2, and Hammersmith, St. Pancras, and Stepney 1 each: last week the 5 cases occurred in Fulham, Kensington, Paddington, Wandsworth, and St. Marylebone.

Primary and Influenzal Pneumonia

A further increase in the notifications of primary and influenzal pneumonia was recorded in England and Wales during the week under review—483, compared with 453 in the previous week—but in London there was a decrease—38 (47). The counties with the greatest increases were: Derby 17 (12), Durham 26 (19), Lancashire 92 (70), Middlesex 18 (11), Warwickshire 38 (35). The number of deaths fell considerably in the 126 Great Towns of England and Wales (from 22 to 12), while in London they remained at 2.

Diphtheria and Scarlet Fever

There was a rise in the notifications of diphtheria in England and Wales and in London during the week under review—1,288 (1,166) and 138 (125) respectively. The centres chiefly affected were: Plymouth 15 (10), South Shields 28 (18), Easington 27 (17), Liverpool 65 (16), Manchester 32 (17), Battersea 9 (1), Fulham 8 (1), St. Pancras 9 (6), Tottenham 7 (2), Uxbridge 8 (0), Croydon 12 (7), Bradford 13 (5), Doncaster 10 (2), Leeds 28 (19), Sheffield 30 (14), Swansea 8 (4). In Scotland, also, an increase was recorded: Glasgow 72 (71), West Lothian 15 (8), Edinburgh 12 (19), Aberdeen 13 (9), Lanark County 10 (10). Of the 27 deaths in the 126 Great Towns of England and Wales 3 occurred in Leeds, and 2 each in Harrow, Liverpool, Birmingham. There were 5 (4) deaths from diphtheria in the 16 principal towns of Scotland during the week—2 each in Glasgow and Ayr and 1 in Paisley.

Notifications of scarlet fever in England and Wales and in London rose during the week under review—1,942 (1,734) and 186 (180) respectively; the centres in which the chief increases were recorded are: Stockport 11 (4), Plymouth 11 (2), East Ham 10 (5), Bristol 29 (23), Bexley 6 (0), Liverpool 42 (35), Battersea 10 (5), Bethnal Green 19 (12), Poplar 12 (5), Ealing 8 (4), Newcastle 21 (13), Wolverhampton 16 (4), Merton and Morden 10 (1), Birmingham 48 (31), Middlesbrough 19 (7), Swansea 11 (2). There was one death (in Carlisle) from scarlet fever in the 126 Great Towns during the week. In Scotland the notifications fell from 389 to 355 during the week under review: 1 death—in Paisley—was reported from the 16 principal towns.

Measles and Whooping-cough

There were no deaths from measles in the 126 Great Towns of England and Wales during the week. Of the 26 (24) cases of measles notified in the administrative county of London the chief were in Hackney 4, Wandsworth and Greenwich 3 each, Kensington, Fulham, St. Pancras, Bethnal Green, and Lambeth 2 each. In Scotland the notifications fell from 17 to 8 during the week under review, with no deaths. Of the 3 deaths from whooping-cough in the 126 Great Towns, 1 each occurred in Bradford, Birmingham, and Ipswich. In London 70 (43) cases were notified, distributed mainly as follows: Islington 10, Stepney 9, Lambeth 6, Poplar 5, Camberwell, Deptford, and Battersea 4 each. In Scotland there was a drop in the notifications from 109 to 91 in the week under review; no deaths were recorded.

Cholera: Plague

During the week ended October 15 there were 361 (280) cases of cholera and 161 (135) deaths in the United Provinces of India and 1,455 (1,670) cases and 702 (743) deaths in the Central Provinces; in Bombay Presidency 381 (267) cases were reported and 161 (95) deaths. In China during the same week there were 82 (95) cases and 24 (33) deaths in Shanghai, and 16 (9) cases and 7 (6) deaths in Hong Kong.

In India during the week under review there were 144 (141) cases of plague and 18 (4) deaths reported in the Central Provinces, 33 (37) cases and 26 (31) deaths in Burma, 30 (23) cases and 12 (12) deaths in Madras Presidency, and 13 (11) cases and 4 (8) deaths in Bombay Presidency.

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 15, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.
† All in Belfast.

‡ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Universities and Colleges

UNIVERSITY OF OXFORD

The Board of Management has elected C. W. M. Whitty, B.M. (Brasenose College), to the Theodore Williams Scholarship in Pathology, 1938.

In Congregation on October 18 the degree of M.A. was conferred by decree upon Edward Stephens Duthie, M.B., M.Sc., Ph.D. (Dub.), May Reader in Medicine and university demonstrator and lecturer in pathology.

UNIVERSITY OF CAMBRIDGE

The Council of the Senate has appointed Professor E. D. Adrian, M.D., F.R.S., a governor of the Darwin Trust until July 30, 1942.

A series of lectures on problems related to the biology and chemistry of food preservation will be given at the Low Temperature Research Station at 5 p.m. each Wednesday from November 2 to November 30.

A public lecture will be given in the lecture theatre of the Physiological Laboratory on Thursday, November 3, at 5 p.m., by Professor Otto Loewi, formerly of the University of Graz. Subject: Action and Discovering of Drugs.

UNIVERSITY OF LONDON

At a meeting of the Senate, held on October 19, the title of Professor in Dental Surgery was conferred on W. E. Herbert, M.R.C.S., L.D.S., in respect of the post held by him at Guy's Hospital Medical School.

The Chester Beatty Scholarship in Radiology of the value of £400 for one year has been awarded to E. P. Allen, M.B., Ch.B. This scholarship was established through the generosity of Mr. A. Chester Beatty for two years to enable students to study radiology in the United States.

The John Marshall Fellowship of the value of £500 a year for two years was awarded to K. C. Eden, M.B., B.S., F.R.C.S. This fellowship was established under the will of the late Miss A. B. Marshall in memory of her father, Professor John Marshall.

KING'S COLLEGE

It has been arranged for Dr. A. Daleq, professor of anatomy in the Université Libre de Bruxelles, to give a further lecture on "The Formation of the Pronephros and its Causes" at King's College, Strand, W.C., on Thursday, November 10. This lecture is in addition to the one announced in this column on October 8, which will be delivered on November 8.

UNIVERSITY OF LEEDS

On October 19 the Court decided to confer the following honorary degrees on January 17, 1939, when the new Chancellor of the University, the Duke of Devonshire, will be installed:

L.L.D.—Sir James Baillie, ex-Vice-Chancellor of the University of Leeds.

D.Sc.—Dr. J. S. B. Stopford, F.R.S., Vice-Chancellor of the University of Manchester; Sir John Ledingham, F.R.S., director of the Lister Institute.

At a meeting of the University Council Mr. P. J. Moir was appointed Professor of Clinical Surgery, in succession to Mr. L. R. Braithwaite, resigned.

UNIVERSITY OF MANCHESTER

Dr. J. C. Brundret has been appointed assistant lecturer in bacteriology, and Dr. S. G. Abelson chief medical assistant in the Department of Clinical Investigations and Research in succession to Dr. Benjamin Portnoy, who has resigned.

The following candidates have been approved at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—J. S. Parkinson, Helen E. Smith, R. C. Webster.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., B.Ch. have satisfied the examiners in the subject indicated:

HONOUR.—J. M. Bowen, Mary W. Bowen, *Marjorie E. Bright, C. Davies, *G. R. Davies, G. C. D. Evans, D. B. E. Foster, W. H. Harris, J. C. Herapath, G. E. Hosking, H. R. Hudd, Elizabeth G. Jenkins, H. V. Jones, *C. W. D. Lewis, *G. O. Lewis, Mair

Llewelyn, *R. M. Marshall, C. J. Morgan, Margaret Morgan, Josephine Parnell, Margaret Parry, J. L. Rees, C. Thomas, Margaret R. Wade, Llary M. Williams, W. Williams.

* With distinction.

The following candidates have satisfied the examiners at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—Part II: R. M. Dykes, E. W. Kinsey.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on October 18, with Mr. W. J. Stuart, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

A. D. Popat, R. L. Allan, A. T. Andreasen, J. G. Barrett, H. J. Beard, I. N. Blusger, S. C. Bose, W. D. A. Callam, E. D. O. Campbell, C. W. S. Dun, G. B. W. Fisher, E. Flatow, H. F. P. Grafton, R. W. W. Hardie, C. C. Harvey, A. E. Jowett, O. C. Lord, R. I. Mahadevan, G. J. H. Maud, J. S. Maxwell, P. T. Millard, W. J. Moody, M. L. Pan, F. Rahman, M. V. Ramanamurti, D. E. Stephens, S. L. Swartz, J. H. Symington, R. K. K. V. Tampan, R. K. A. van Someren, J. S. Visser, J. L. D. Williams.

At the annual meeting of the College, held on October 19, the following officers were elected for the ensuing year:

President, Mr. W. J. Stuart. Vice-President, Mr. Henry Wade. Secretary and Treasurer, Mr. J. W. Struthers. Representative on the General Medical Council, Mr. Alex. Miles. Convener of Museum Committee, Dr. A. Logan Turner. Librarian, Mr. S. M. Traquair. Conservator of Museum, Mr. C. F. W. Illingworth.

Medical News

The hundredth dinner of the Aberdeen University Club, London, will be held at the Café Royal on November 17. Any graduates wishing to attend should apply to Dr. Andrew Topping, County Hall, S.E.1.

A sessional meeting of the Royal Sanitary Institute will be held at the Dorothy Café, Sidney Street, Cambridge, on Friday, November 4, at 5 p.m., when Dr. R. D. Tompkins will give an address on "Recent Work in Food Preservation," and a discussion on "The Prevention of Droplet Infection, with Special Reference to Streptococcal Disease" will be opened by Dr. W. H. Bradley.

Owing to the recent international crisis, the meetings of several medical societies in France have been postponed (see *Journal*, October 22, p. 872). The forty-seventh Congress of French Surgery, which was to have been held in Paris in the first week of October, has been deferred to a later date.

Owing to the crisis the second International Congress of Radio-aesthesia, which was to have been held in Paris from October 17 to 19, has been postponed to November 7 to 9. Further information can be obtained from the Secretariat, 9 rue Etex, Paris 18e.

The French Academy of Medicine is prepared to award a prize of 10,000 francs for an original study of the therapeutic properties of olive oil. Entrants for this competition must either give an account of a new curative action on the part of this oil or throw new light on its already known therapeutic properties.

The September issue of the *Bulletin de l'Office International d'Hygiène Publique* includes articles on female employees and tuberculosis in Yugoslavia, renal tuberculosis, tuberculosis in India, standard methods for the preparation of tuberculin, anti-tuberculous vaccine, and immunization against yellow fever.

The October issue of the *British Journal of Dermatology and Syphilis* is a jubilee number (1888-1938) containing retrospective articles by Dr. J. M. H. Macleod, Dr. James H. Sequeira, and Sir Ernest Graham-Little, with portraits of editors of the journal and of celebrated British dermatologists of the past fifty years.

As we go to press we learn with deep regret that Sir Robert Johnstone, who presided over last year's Annual Meeting of the British Medical Association, died at Newcastle, County Down, on October 26.

At the general meeting of the Governors of The Retreat, York, Dr. Arthur Pool was appointed medical superintendent in place of Dr. Neil Macleod, whose resignation was regretfully accepted a few months ago. Dr. Pool for the past five years has been medical superintendent of the South Yorkshire Mental Hospital at Sheffield.

Dr. C. S. Myers, F.R.S., successively Director and Principal of the National Institute of Industrial Psychology since its foundation in 1921, retired from the active direction of its work on October 1. He has, however, accepted the honorary post of its scientific adviser, which will maintain his past contact with the scientific aspects of the industrial and vocational work, and in which he will continue to supervise its research activities and publications.

Dr. L. Haden Guest, M.P., left London for Lagos on October 19 with other members of the Commission which is to report on the interrelationship between Government officials, traders, and natives in the West African Colonies and the general development of resources.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Ailiology Westcent, London.*

SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Intratracheal Adrenaline for Relief of Asthma

Dr. S. H. KUTAR (London, S.E.18) wishes to know if other readers have tried intratracheal instillation of adrenaline for "hyperacute" cases of asthma, and with what results. He has used this treatment in a very small number of cases with great relief of symptoms and without misadventure. The patients in question are those with much respiratory distress, fighting for breath and gradually becoming more cyanosed, and unrelieved by ordinary measures, even morphine. After preparation of the skin of the lower half of the neck a 5 c.cm. all-glass syringe, with a fairly wide-bored needle, is loaded with 2 c.cm. of 1 in 1,000 adrenaline solution. A point is chosen in the mid-line of the neck about a quarter of an inch below the cricoid cartilage, and the detached needle is inserted at right angles to the anterior plane of the neck, entering the trachea between its first and second rings. The loss of resistance and the peculiar sound of air rushing in and out of the needle indicate that the trachea has been entered. After making sure that no blood emerges from the needle, the syringe is mounted on it and the solution injected quickly. Syringe and needle are at once withdrawn and the puncture is sealed with collodion. The spasm of coughing soon subsides, and within two minutes of injection the breathlessness and distress disappear.

Gangrene of the Colon in an Infant

Dr. L. A. LEDINGHAM (Kirkcaldy) writes: Perhaps the following rather unusual case may be of interest to your readers. The patient was a full-time 8½ lb. male, a lusty infant which had been delivered rapidly and spontaneously. It was breast-fed, and did well, apart from a little regurgitation after feeds, for four or five days, after which time it was reported to be feeding badly in spite of a superabundance of breast milk, and to be rather fretful. By the seventh day the infant had lost 2 lb. of its original birth weight. From the fifth day the abdomen had been rather distended, especially in the hypogastric region, and the stools assumed a very slight greenish tinge and were rather loose. There was no sickness, and examination revealed nothing else abnormal. The child lost weight rapidly and died on the eleventh day. At necropsy the abdominal distension was found to be due entirely to the large bowel, which for some unknown reason was greatly distended and full of practically normal faeces. There was at the hepatic flexure a patch of well-marked gangrene the size of a sixpence, with a small perforation; there was peritonitis involving the paracolic gutter, caecum, appendix, and pelvic organs, with a fair amount of turbid free fluid. The abdominal organs were otherwise macroscopically normal, and the chest contents, apart from a defective closure of the ductus arteriosus, were healthy. I should value any opinions as to the possible causation of this condition and the treatment which might be undertaken in such a case.

Treatment of Pruritus Ani

Dr. C. HORWITZ (London, N.1) writes: I think "J. M." will find that a cure can be brought about easily and rapidly by methods much simpler than those he has employed and proposes to employ. The patient should be instructed to avoid toilet paper, and make use instead of a small soft sponge which has been wrung out in a mild disinfectant such as dettol (1 drachm to a pint of water). The sponge should be thoroughly cleaned and the water changed every second day. The occasional use of toilet paper when the patient is away from home cannot be avoided and does not seem to matter much.

"J. C." writes: Has "J. M." tried "belzema" ointment and soap (sold by Brooks and Warburton, Ltd., 232, Vauxhall Bridge Road, S.W.1)? An extreme case, the worst I have seen, resisting the usual treatment, including x-ray therapy, cleared up entirely on treatment with this soap and ointment.

"A. G." also writes: If "J. M." has not included ung. metallorum in his "innumerable local applications" for pruritus ani, he should try it.

Income Tax

"Back Duty" Paid—Allowances Due

"D." entered into a partnership in August, 1932. His partner was negotiating a "back duty" settlement, and for some years income tax payments were made "on account" with apparently a subsequent lump-sum payment in settlement of all tax to 1936-7 inclusive. "D." now finds that some life assurance relief was not allowed for in the settlement, and neither was the fact that his wife was receiving £52 per annum from the firm for assisting in violet-ray, etc., treatment. The inspector declines to reopen the settlement.

*. It is possible that the terms of the settlement were final and binding, and therefore that "D." has no legal remedy. But we advise him not to leave the matter as it stands. The settlement was negotiated on the basis of certain figures and certain definite allowances. If these have now proved unfair to "D." we think the settlement might be reopened, if not as regards both questions at least as regards the life assurance relief, which can be claimed within six years of the end of the year of assessment concerned. The deduction for the £52 is on a somewhat different footing, as it relates to the computation of the profits and there may have been some give and take over those figures when the settlement was agreed. We advise our correspondent to write, placing the facts before the Secretary, Board of Inland Revenue, Somerset House, W.C.2.

LETTERS, NOTES, ETC.

Spontaneous Version of Transverse Presentation

Dr. A. FRANKLIN (Liverpool) writes: About three weeks ago I was approached by a midwife and asked whether I would visit a patient of hers and give an opinion on her condition. On arriving at the patient's home I found that she was in bed and was informed that the membranes had ruptured naturally at 11 a.m. the same day. The baby was lying with its head in the left iliac fossa and the breech in the right iliac fossa; the foetal heart was distinctly audible below and to the left of the umbilicus. On vaginal examination the os was rigid and rather less than two fingers dilated, and protruding through it into the vagina was the right hand of the baby. I decided to perform internal version and bring down a leg. On returning a short time later prepared to do this, I was surprised to find that version had occurred spontaneously, the position being that of a breech. The woman had had no pains. The head was now lying in the fundus, and on vaginal examination the hand had completely disappeared and the breech was easily recognized. The degree of dilatation of the cervix was still the same as before. Pains began about midnight, the presentation being that of a breech with extended legs. The baby was born alive at 5.15 a.m. and weighed exactly 8 lb. The case appears to be unusual, as spontaneous version occurred after rupture of the membranes and prolapse of the arm.

Acute Spreading Emphysematous Gangrene

Dr. T. J. KILGALLAN (Boyle, Eire) writes: There may be nothing very atypical about this case, but the condition is so rare, at any rate in the West of Ireland, that a report of it may be of interest. The patient, a robust woman, aged 43, had been ill for ten days, during which period she complained of a "swelling" and severe pain in the right side. When I saw her she had a temperature of 103.5° F. and a pulse rate of 110. Her tongue was very dry and dirty and her respirations were fast; she was cyanosed and appeared to be suffering from a profound toxæmia. On examination there was a tumour about the size of a half-melon on the right chest in the posterior axillary line. This was tympanitic on percussion, and evidently contained gas and a small amount of fluid. There was a brawny swelling extending downwards, involving the tissues of the right loin and hip, and upwards, invading the tissues of the shoulder and chest wall as high as the clavicle. The skin over the swelling was a dusky red colour. On palpation the typical crepitations of emphysema could be felt in parts, but especially over the upper chest. Aspiration of the tumour confirmed that it contained gas and a small amount of very foul-smelling dark grey fluid. The lungs and pleura were normal. I much regret that, owing to lack of convenient laboratory facilities, the fluid had not been examined with a view to isolating the causative organism. Apparently this organism entered the chest wall through an unnoticed scratch or abrasion. I felt that treatment of any kind would be of no avail. The patient died four days later.

Children Alone in the Dark

The annual report for 1937-8 of the National Society for the Prevention of Cruelty to Children draws attention to the growing tendency of parents to leave young children alone in houses for many hours, especially at night. This practice may be attributed to changing social conditions. Contributory factors are the lure of the cinema and other amusements, the difficulty of securing domestic servants, and the increasing number of families where parents live with their children without the company of other adults. As a result of old age pensions and the larger number of houses available grandparents, who formerly lived with their descendants, nowadays are able to keep up separate establishments. The report stresses the mental cruelty inflicted upon a young child who wakes alone in a dark deserted house, and points out that profound and prolonged after effects may supervene. Distressing tragedies may also occur. In the course of the year under review four young children were burned to death at Gravesend during their parents' absence and three at Dunston-on-Tyne. The inspectors of the Society have been uniformly successful in dealing with the parents in these cases, which are usually the result of lack of thought rather than of deliberate neglect.

A Delivery Towel for Midwifery

Mr. ERNEST B. HINDE (Norwich) writes: With reference to the articles on puerperal sepsis in the *Journal* of August 13 (pp. 331 et seq.), it occurs to me that a device which I have found most useful may be equally useful to others. It is a delivery towel. The end of an ordinary towel is turned back and sewn along the edges, so as to make a pocket about 18 inches long. This lies over the abdomen as the woman lies in the left lateral position. The towel is long enough for the other end to hang down over the buttocks. I insert my gloved hand in the pocket and can use pressure as necessary until the head is crowned. Then I withdraw my hand from the pocket and have both hands ready for the delivery of the head. I think this is much better than wrapping one's hand in a towel, which very easily, especially with a restless patient, becomes disarranged.

George III

Dr. JAMES R. WHITWELL writes: The notes of Dr. W. R. Betts on the case of George III (*Journal*, September 24, p. 664) are most interesting. I should, however, like to suggest that he pays His Majesty a compliment which was hardly deserved by saying that he was intelligent. Lecky (*History of England*) certainly does not agree, for he says, "His education was indifferent, and as an adult he was singularly deficient in literary culture." Lord Waldegrave said that he was "a boy of respectable abilities, but great constitutional indolence." J. R. Green (*Short History of the English People*) says, "He had a smaller mind than any English king before him save James II, he was wretchedly educated, and his natural powers were of the meanest sort." Dr. Thomas (Bishop of Peterborough, and his tutor) said, "He is remarkably backward, his stock of general knowledge at aet. 22 [when he ascended the throne] was very slender, he knew no Latin or Greek [most unusual at that time], he wrote English ungrammatically"; he used to swing himself to and fro when talking, and had a trick of ending his sentence with "What! what!" His taste was execrable, according to Madame D'Arblay (*Diary and Letters of Miss Burney*), and he regarded Shakespeare as "sad stuff."

Frederick Page of Newcastle

Professor G. GREY TURNER writes: I have been looking through some numbers of the *B.M.J.* which accumulated while I was travelling to Australia last year. In the leading article on "Spinal Tumours: A Jubilee" in your issue of July 31, 1937 (p. 220) you speak of Herbert Page of Newcastle-on-Tyne and of a rather unhappy prediction which he made concerning the operation of laminectomy. Herbert William Page practised in London, where he was surgeon to St. Mary's Hospital. For years he was prominent as a railway surgeon, and wrote much on spinal injuries. The Newcastle surgeon was Frederick Page, also a railway surgeon; but though ready with his tongue he was reticent with the pen and wrote little.

Christmas Cards

It is not often that help for a deserving charity is forthcoming from the performance of so pleasant and individual a custom as sending greeting cards at Christmas, but the opportunity is once again provided by the Grenfell Association of Great Britain and Ireland. As last year, the association has for sale a number of specially designed Christmas cards, some in black-and-white, and one, entitled "Christmas Eve in Labrador," in full colour. Prices for these cards, which are sold in aid of Sir Wilfred Grenfell's medical work among British settlers in Labrador and Newfoundland, range from 1s. 6d. a dozen to 3s. for half a dozen. Further particulars and a leaflet showing the designs, and other gifts made by the people of Labrador, may be obtained from the Grenfell Association, 66, Victoria Street, London, S.W.1, or, in Scotland, from the Hon. Mr. John Scott MacLay, 21, Bothwell Street, Glasgow.

A Calendar of Medical History

Warner's *Calendar of Medical History* endeavours to discover new phases in the annals of medicine that may lend fresh interest to browsing among out-of-the-way crevices of the past. The practical features have been retained in the 1939 edition, with occasional additions of modern interest. This diary will be available early in December to members of the medical profession only. Those who have found it useful and would like to receive a copy are advised to apply early to Power Road, Chiswick, W.4.

- Chronic Acne Vulgaris (Indurata) in Middle-aged Women. A. H. Pirie.—p. 171.
- Treatment of Constipation. H. G. Bird.—p. 172.
- Paroxysmal Tachycardia. W. F. Connell.—p. 173.
- Insulin Therapy in Future of Psychiatry. M. Sakel.—p. 178.
- Vitamins in Infancy and Childhood. F. F. Tisdall.—p. 179.
- Early Vaccination in British North America. R. C. Stewart.—p. 181.

Prolonged Artificial Respiration.—The necessity for prolonged artificial respiration in cases of drowning, asphyxiation, and electric shock is emphasized. A case of electric shock is recorded in which this procedure was carried on for eight hours before the patient was safe. In a series of cases of electric shock studied by one of the authors it was found that when artificial respiration was started within one minute of the shock 90 per cent. of the patients recovered, when there was a delay of six minutes only 10 per cent. were resuscitated.

Deutsche Medizinische Wochenschrift

Berlin vol. 64 August 12, 1938

- Biological Medicine and Nutritional Therapy. S. Bommer.—p. 1169.
- Treatment of Chronic Epidemic Encephalitis (Parkinsonism): Bulgarian Cure with "Homburg 650." H. D. v. Witzleben and A. Werner.—p. 1174.

- Lumbar Puncture in Out-patients. D. Erskine and A. G. Johnson.—p. 371.
- Gonococcal Ophthalmia treated with 2-(p-aminobenzenesulphonamido)-pyridine. A. M. Michie and M. H. Webster.—p. 373.
- Two Testicles in One Inguinal Hernia. D. O. Davies.—p. 373.

Sulphanilamide in Gonorrhoea.—Detailed analysis of some 500 cases in males and 150 in females showed that twenty-one days' suitable treatment by sulphanilamide led to cure in 80 per cent. (males), with about one-seventh the usual rate of complications. A technique is described which must be closely followed. It includes the use of vaccines and excludes use of the drug before the eighth to tenth day. Uleron is thought to be less effective than sulphanilamide, and to carry considerable risk of severe peripheral neuritis.

- Manipulative Surgery. W. Hughes.—p. 83.

presence of living tubercle bacilli in obsolete lung lesions. Caseous or calcified material from Ghon foci and hilar lymph nodes was cultivated and injected into guinea-pigs. There was only one positive result. This finding is inconsistent with the hypothesis that endogenous reinfection occurs in adults. There may be histological signs of activity in these lesions although tubercle bacilli are absent; silica is frequently present in excess, and this may account for such changes.

American Journal of Syphilis, Gonorrhea and Venereal Diseases

St. Louis vol. 22 September, 1938

- Present Status of Epidemiology of Gonorrhoea. R. A. Vonderlehr and I. J. Usilton.—p. 537.

*Prevention and Treatment of Neurosyphilis by Combined Artificial Fever and Chemotherapy. Results in Seventy-two Cases of Asymptomatic and Clinical Neurosyphilis. A. E. Bennett and M. D. Lewis.—p. 593.
Acquired Syphilis of Infancy and Childhood. Thirty-five Cases. J. R. Waugh.—p. 607.
Syphilis Control in Chemical Industry. G. H. Gehrmann.—p. 623.
Ecthyma of Vulva Simulating Condyloma Latum. H. M. Robinson.—p. 631.
Chancroidal Infections in Female. R. Torpin and R. B. Dienst.—p. 634.
Intravenous Aldersone in Treatment of Neurosyphilis. G. R. Kamman.—p. 638.

Prevention and Treatment of Neurosyphilis.—Routine cerebrospinal fluid examination in the first year of infection reveals asymptomatic neurosyphilis; if this does not yield to ordinary chemotherapy, fever treatment should be given in addition. In ten cases of asymptomatic neurosyphilis treated by the combined method seven showed complete and two partial reversal of the previous cerebrospinal fluid findings. In nineteen cases of general paralysis of the insane similarly treated fourteen showed complete and three partial remission, while two were unimproved. In thirty-one cases of tabes of a severe type sixteen had complete relief, eleven were improved, and four were unimproved. No success was obtained in three cases of Charcot joints. In twelve cases of severe disabling meningovascular syphilis ten had complete and one partial relief, and one was unimproved.

Annales de Médecine

Paris vol. 44 July, 1938

- Normal and Pathological Content of Tyramine in Blood. M. Loeper, A. Lesure, and A. Netter.—p. 85.

*Voice Disturbances of Resonance. L. Labarraque.—p. 605.
*Pathography of Mastoid Processes as Operative Indication in Acute and Chronic Mastoiditis. L. Baldebeck and J. Leroux-Robert.—p. 613.

Otitis in Aviators.—The author has found that pilots in chase planes are particularly liable to middle-ear disturb-

ances. This is due to the sudden changes in air pressure, as the planes have to climb and descend very rapidly. The intense cold at high altitudes is also a contributory factor. There is a description of the various measures and protective apparatus which help to guard against these complications.

Paris vol. 8 August, 1938

- Contribution to Study of Audiometry. M. Aubry, J. Causse, and L. Chavary.—p. 689.

Case of Paralysis of Glossopharyngeal Nerve due to Deep Ulceration of Tongue. H. Solomovici and M. Segal.—p. 747.

Sedimentation Test.—The sedimentation rate of the red blood corpuscles is a criterion of tissue destruction. The higher the figure for the sedimentation rate the more active is the tuberculous infection. The author recommends that the test should be applied in all cases of tuberculosis of the larynx before treatment of the lesions by galvano-cautery is undertaken.

Syphilitic Optic Neuropathies.—The field defects of patients with primary syphilitic atrophy of the optic nerve fall into four categories: (1) concentric contraction of the peripheral field with late visual loss; (2) sector defects with early or late visual loss; (3) central or cecocentral scotoma with normal peripheral fields and early visual loss; and (4) central or cecocentral scotoma with peripheral defects and early visual involvement. Field changes may also precede atrophy of the disk, while homonymous defects are due to cerebral trauma or arteriosclerosis. The lesion in syphilitic atrophy probably lies between the chiasma and the globe.

 Use of Hyoid Bone as Graft in Laryngeal Stenosis. E. A. Loeper.—p. 106.
 New Method of Operation for Congenital Atresia of Posterior Nares. J. C. Donnell.—p. 112.

Streptococcal Mastoiditis.—In acute streptococcal mastoiditis the author advises that operation should be delayed until localization of the infection has occurred. He contrasts the results of immediate and delayed operations, and shows that when expectant treatment is adopted there are fewer complications, a lower mortality, and a shorter period of hospitalization.

Improved Hearing in Otosclerosis.—Sourdille's operation for otosclerosis only gives a temporary improvement because the labyrinthine fistula closes after a time. The author claims that his new operation, which is described in great detail, provides a mechanical means of keeping the newly created fenestra in the external semicircular canal permanently open. The results of operation on twenty-three patients with otosclerosis are described. In nineteen cases a good practical improvement in hearing was obtained and maintained. In four cases in which operation was performed in spite of poor existing bone conduction, no improvement in hearing was obtained.

 Recovery of Patient with Type III Pneumococcus Meningitis of Otitic Origin. J. Gubner.—p. 241.

Cancer of Larynx.—This is a statistical and histological study of 102 cases, tabulated under two headings—laryngectomy and laryngofissure. The recurrence rate in cases of subglottic cancer is very high, and therefore total laryngectomy is preferable to laryngofissure in its treatment.

Objective Tinnitus.—Three cases of this rare condition are reported. The chief causative factor is clonic contraction of those soft palate muscles which regulate the opening and closing of the Eustachian tube. The peculiar clicking sound accompanies alternate separation and contact of the two moist surfaces. Other factors which may produce objective tinnitus are disturbances of the vascular system about the head and neck—for example, aneurysms.

Vaccination of Newborn.—Small-pox is most fatal in the early years of life, but an infant under the age of 3 months is not likely to develop the disease even in an epidemic. Vaccination after exposure must be done early to be of value. All infants should be vaccinated early, and nearly all can be vaccinated successfully if a sufficient number of attempts are made. The use of glycerinated calf lymph has done much to obviate such dangers as erysipelas and syphilis. The only contraindications are eczema, which seldom appears before the infant is 6 months old, and much debility. Post-vaccinal encephalitis is discussed.

Cancer in Ontario.—This is a statistical review of the cancer problem in Ontario, where this disease ranks second as a cause of death, being responsible for 11.8 per cent. of all deaths. The death rate rises rapidly with age—60 per cent. of deaths under 70 years and 34 per cent. under 60 years are due to cancer. More than half the deaths are attributable to cancer of the digestive system. In females cancer of the breast ranks first in numerical importance, in males gastric cancer. In over a quarter of all cases the primary cancer is "accessible." The general evidence suggests that incidence of cancer is not increasing, and that one-third of the apparent increase may be attributed to "ageing" of the population.

Laughlin Test.—This is a comment on the utility of the test first described in the *Canadian Medical Association Journal* of August, 1935. It is a precipitation rather than an agglutination test, is performed on slides, and the result may be read with or without a microscope. An antigen and two reagents are required, one a "stock" or stable reagent, and a test or "active" reagent.

which is to be recently prepared from stock, the process being described. It is claimed that this test possesses the advantages of simplicity, speed, stability of its reagents, and adaptability to emergencies.

Panniculopathic Crisis of Blood. H. Otto.—p. 90.

B.M.R. in Chickens.—Haldane's gravimetric method, which was used in these experiments, gave the basal metabolic rate of chickens, 75 to 130 days old, as somewhat higher than that reported in the literature. In chickens affected with fowl paralysis it was found to be normal; birds with transmissible fowl leucosis had a moderately elevated rate. In cases of fibrosarcoma the basal metabolism was not greatly increased. In three cases of lymphocytoma (one atypical) and in one case of myelomata it was, on the other hand, considerably increased.

Serum Phosphatase in Jaundice.—Whether jaundice was present or not, the serum phosphatase in dogs was increased in several forms of liver injury and biliary obstruction. Generally, obstructive jaundice gave a higher serum phosphatase than a hepatitis. A rise in serum phosphatase was a more sensitive indication of hepatic injury than a rise in serum bilirubin. The authors infer that biliary phosphatase originates in the liver, and that in liver disease a high serum phosphatase indicates the leakage of biliary phosphatase into the blood stream.

Crystalline Factor I.—The alcoholic extract of a concentrated baryta-free solution of the baryta eluate of the fuller's earth absorbate from rice bran extract was treated successively with baryta, mercuric chloride, and lead oxide, and then cleared of these metals. From the resulting solution Factor I was obtained as phosphotungstate, which crystallized in the form of square plates and from which a solution of free Factor I was obtained by treating with baryta. After concentration of this solution and treatment with alcohol and acetone, Factor I crystallized in colourless needles in rosette or fan shapes. The crystals readily cured acrodermatitis in rats, with simultaneous resumption of growth. Being colourless and not absorbed by lead sulphide, Factor I does not resemble flavin phosphoric acid.

Inhibition of Benzidine Reaction.—Ascorbic acid in sufficient concentration inhibits the benzidine reaction with haemoglobin. Added to a positive test mixture it reverses the reaction and gives a colourless mixture. These effects are produced by ascorbic acid, although in a weaker manner, etc.

when it has been oxidized by potassium permanganate. For clinical work the interference of ascorbic acid may be prevented by performing the benzidine test on the ether extract of acidified urine.

Ultra-violet Light and Rickets.—Of ultra-violet light of six different wave-lengths, light of wave-length 2804 A.U. was most effective and light of wave-length 3128 A.U. was least effective in curing rickets in rats. Antirachitic efficiency roughly follows the absorption curve of ergosterol and is roughly inversely proportional to erythema effectiveness.

Nicotinic Acid and Chick Dermatitis.—Nicotinic acid and its amide failed to prevent or cure dermatitis in chicks fed on a heated ration of natural grains and casein, and had no marked influence on the growth of chicks on a modified Goldberger diet. Liver extract, however, contained an anti-dermatitis factor which is distinct from vitamin B₁, vitamin B₂, riboflavin, nicotinic acid, and factor W.

*Urinary Cholesterol in Cancer. E. Bloch and H. Sobotka.—p. 567.

Cobalt in Anaemia.—Cobalt is a general contaminant of iron compounds. In view of recent work demonstrating that cobalt is active in exceedingly small quantities, and since comparatively large doses of this element may play a part in inducing polycythaemia, the possibility that cobalt might be concerned in some way in the treatment of milk anaemia of the rat with common iron salts plus copper was investigated. No increase in growth or haemoglobin regeneration was obtained in rats fed on whole cow's milk plus copper, manganese, cobalt, and purified cobalt-free iron as compared with rats on a similar diet without added cobalt. Underwood and Elvehjem conclude that the small amounts of cobalt which contaminate all iron salts play no significant part in the treatment of milk anaemia in the rat.

Urinary Cholesterol in Cancer.—Tumour tissue is richer in cholesterol than any parenchymatous organ, except perhaps the brain. Urines from cancer patients contain about ten times as much cholesterol as urine from normal controls. Hypercholesterolemia occurs also in kidney disease, and possibly during pregnancy. Normal cholesterol values are found

in cachectic patients with such other diseases as tuberculosis and cardiac disease. Two possible causes for the appearance of cholesterol in urine in cancer are discussed, and the authors seem to prefer the explanation which suggests that this hypercholesterolemia is due to the destruction of tumour tissue rich in cholesterol.

Effect of Simultaneous Inoculation with Various Micro-organisms on Pathogenesis of St. Louis Encephalitis in Mice. E. A. Cook.—p. 127.

Bacteriophage Activity in Blood.—The lytic action of bacteriophage is not exerted *in vitro* in the presence of blood, but treatment with bacteriophage has nevertheless been found effective in some forms of septicaemia. Experiments are reported here in which bacteriophage exerted an opsonic effect, and it is suggested that this mechanism may be responsible for such therapeutic successes.

Lowered Resistance to Pneumonia.—An excess of mucin in the bronchi favours the multiplication of pneumococci and may be a factor determining the onset of pneumonia. It was found in experiments on rats that severe chilling or alcoholic intoxication inhibits closure of the glottis, thereby favouring the aspiration of mucin. It is suggested that this mechanism may form part of the basis of what is vaguely described as "lowered resistance" to pneumonia.

Subphrenic Abscess in Children.—Ten cases in children are reported in detail. The x-ray examination is an important adjunct to the history and clinical findings, and seldom fails to make the diagnosis clear. Fixation of the diaphragm is the earliest sign, and later there is an accumulation of fluid, which tends to remain small. The majority of cases follow appendicitis, though there is often an interval between the two diseases and the abscess is generally on the right side. Empyema may accompany the subphrenic abscess, due to infection through the diaphragm. Spontaneous recovery may occur without drainage.

Ripe Bananas.—A large number of infants were fed with ripe bananas and the results noted. All the infants were underfed or had suffered from enteritis. The advantage of the banana is that it is very easily assimilated and is thus useful in supplementing the ordinary milk feeds. The article suggests that the banana should be used more widely for complementary feeding in this way.

Hepatic Emergencies.—Hepatic insufficiency is rare because the liver is very resistant to repeated injury and possesses a remarkable power of regeneration. The first principles of treatment are to dilute and eliminate toxic agents and to attempt to restore the normal glycogen content of the liver. Diffuse haemorrhage is due to deficiency in the concentration of prothrombin in the blood owing to the failure to absorb

certain sterols necessary for its formation. This is responsible for the occurrence of the haemorrhagic diathesis in association with jaundice due either to obstruction or advanced atrophy of the liver. Whole bile or bile salts are of therapeutic value.

Complications of Diabetes.—The lengthening life of the diabetic patient due to insulin treatment, the higher incidence of onset over the age of 40, and the ageing of the population in general explain the fact that there is an increasing number of elderly diabetic patients. The death rate is of course higher in elderly persons, although the disease in older persons is not usually of the more severe type. Arteriosclerosis and vascular lesions causing gangrene of the feet following trauma or infection are the most important complications. Diabetic neuritis and retinitis are possible complications, the former being painful and lasting for many months and the latter having no chance of improvement. A carbuncle in a case of diabetes is still serious, and was formerly considered to be always fatal.

 Radiology in Teaching of Pathology. W. Carpenter.—p. 368.
 Report on Cancer of Lip. A. W. Erskine.—p. 372.

Radiotherapy for Tumours of the Testis.—The case histories of 314 patients with malignant testicular tumours are reviewed with special reference to survival following treatment. The most important factors influencing prognosis are the type of the tumour and the presence or absence of metastases at the time of treatment. A patient without metastases has about a 60 per cent. chance of surviving for five years or longer; with metastases his chances are only about 30 per cent.

For Everyday Practice

PRODUCTS OF THE GLAXO LABORATORIES

COLLOIDAL CALCIUM WITH OSTELIN

For treatment of chilblains

Vitamin D in colloidal solution, painlessly given subcutaneously or intramuscularly. Improvement established in chilblains and other capillary vasomotor disorders, and in allergic conditions, often after the first 1 cc.

Boxes of 6 x 1 cc.
ampoules, 5 -
12 x 1 cc. 8 6,
30cc bottles, 10 -

OSTELIN LIQUID

The pioneer vitamin D product

The only preparation of vitamin D completely miscible with water. May be prescribed in all mixtures containing calcium or phosphorus, to ensure assimilation. 5,000 international units in each cc.

4-oz. phials, 2 6;
2-oz. bottles, 7 6;
4-oz., 12/6

VITEOLIN CAPSULES

Vitamin E for spontaneous abortion

Each capsule contains unsaponifiable matter from 5 grams of freshly extracted wheat-germ oil—thirty times the concentration of the oil itself. The only vitamin E preparation used in published British clinical trials.

Boxes of 25, 6 -;
100, 21 -;
500, 80 -

CALDEFERRUM TABLETS

For dietary deficiencies

New threefold safeguard against dietary deficiencies. Iron, calcium and vitamin D in one tablet. Four tablets daily is a simple routine easily carried out. The chocolate coating makes Caldeferrum pleasant to take.

Bottles of 50,
2/6; 100, 4 3;
500, 13 6;
1,000, 19 6.

Sustaining 3-in-1 cereal food

Well-balanced. Provides vitamins A, B₁, D; calcium, iron and other tonic minerals. Digestible in health and sickness alike. Nutritionally safe for weaning. Ready to serve.

Cartons, 1- and 1.9 (double size).

FAREX

ANTIVIRIN NASAL JELLY

For the common cold NEW FORMULA

Antiviruses of organisms usually found in nasopharynx during common cold (content now increased). Ephedrine relieves vascular congestion. Jelly permits effective penetration. Pleasant to use.

Long-nozzle tubes, 1 6

THROMBIN-COAGULANT-MAW DRESSINGS

● FOR THE RAPID CONTROL OF HAEMORRHAGE

T.C.M. Dressings provide a new method of effectively and speedily controlling haemorrhage.

The Dressings are treated with Thrombin-Coagulant-Maw—a stable preparation of Thrombin, the natural clotting agent of blood—which anticipates the formation of Thrombin in normal shed blood and checks even severe haemorrhage within 5-15 seconds.

T.C.M. Dressings are not expensive, they cost, in fact, only a trifle more than ordinary Dressings, but one of these dressings will do the work of perhaps several ordinary dressings, thus proving cheaper in the end and saving you valuable time.

The Dressings are supplied sterile, in sealed drums, ready for use. The series consists of Wound Dressings, Lint Squares; and Lint and Plaster Dressings.

Thrombin-Coagulant-Maw is supplied also in Powder form.

The new Victor F-3 X-ray Unit

Choice of Radiologists in 43 Countries

AMAZINGLY good performance for so small an X-ray unit has already made the new Victor F-3 the choice of radiologists in 43 countries. Its wide range of practical service has been made possible through increasing the X-ray power of the original Victor F by 220%, while retaining the same extremely fine detail in both radiography and screening. This low-priced combination unit is useful not only for auxiliary service in the consulting room, but also as a light-weight portable unit for emergency cases outside.

STUDY THESE FEATURES

Portable and mobile * Wide range * Shockproof * Climate-proof * Easy to use * Operable from any plug point * Highly flexible and adaptable * Compact case only 21 x 14 x 8 inches * Weighs only 45 lbs. * Complete technique charts * Long-life, genuine Victor Coolidge tube * Accurate timer * Foot switch for screening * Convenient terms if desired

For a demonstration without obligation, or the free descriptive booklet, simply fill up and post the convenient coupon.

FOOT COMFORT

By wearing
'APTERNA' HEEL-LESS SHOES

These shoes are designed in the common-sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health.

LANGHAM HOUSE, UPPER REGENT ST., W.1

Charles H. Baber

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by prescribing the correct series of "Apterna" Heel-less Shoes.

"Apterna" Shoes are available for men and women and children.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

for the treatment of eight Ladies, voluntary, temporary, or certified patients.
Large gardens and own dairy

CLIFFDEN, TEIGNMOUTH, for early and convalescent cases. A well-appointed house, with spacious balconies, and extensive views of the South Devon coast. Sub-tropical gardens, own dairy in 25 acres. Private road to beach.

Resident Physicians: BERTHA M. MILES, M.D., B.S. Starcross 59
ANNE S. MILES, M.R.C.S., L.R.C.P. Teignmouth 289

THE COPPICE, NOTTINGHAM

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

TELE: 6417. For terms, etc., apply to the Medical Superintendent.

HAYDOCK LODGE

NEWTON-LE-WILLOWS, LANCASHIRE

Tele: Street, Ashton-in-Makerfield

Phone: Ashton-in-Makerfield 7311.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases, either voluntarily, temporarily, or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

NORTHUMBERLAND HOUSE,

GREEN LANES, FINSBURY PARK, N.4

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy of access from all parts. Six acres of ground, highly situated, facing Finsbury Park. Voluntary and Temporary Patients received without certification. Occupational Therapy, Psychotherapy, and other modern forms of treatment.

Telephone: STAMFORD HILL 2685. Telegrams: "SUBSIDIARY, LONDON."
Convalescent Home, KEARSNEY COURT, DOVER. For further particulars apply to the Medical Sup.

BOWDEN HOUSE,

HARROW-ON-THE-HILL,

For the residential treatment of Functional Nervous Disorders

No case under certificate nor under the M.T.A.

This home, which was founded in 1911, is designed to provide for psychoneurotics a curative environment associated with modern psychological treatment modified to suit each individual patient. The treatment is in the hands of three experienced psychotherapists, and most patients receive three hours of analytical treatment per week. Occupational-therapy of many varieties is available but not obligatory. Recreations include tennis, badminton, billiards, etc.

On admission patients are examined by the diagnostic physician, who advises on all physical treatment. As far as possible all necessary pathological examinations are carried out by the pathologist in the laboratory on the premises.

STAFF:

H. CRICHTON-MILLER, M.A., M.D., M.R.C.P. (Senior Physician). GRACE H. NICOLLE, M.A., M.B. (Resident Physician).
ALFRED TORRIE, M.A., M.B., Ch.B., D.P.M. (Medical Superintendent). MARY HALL, M.B., B.Ch. (Pathologist).

LAVERSTOCK HOUSE

SALISBURY

WILTS

PRIVATE MENTAL HOME FOR LADIES AND GENTLEMEN.

Completely up to date. Lovely house and grounds (18 acres). Certified and uncertified cases taken. Facilities for going to the seaside.

ESTABLISHED OVER 200 YEARS.

Apply to Med. Supt. for illustrated brochure.

Tel.: SALISBURY 2612.

CHEADLE ROYAL HOSPITAL

CHEADLE, CHESHIRE.

This REGISTERED HOSPITAL, with a SEASIDE BRANCH at Colwyn Bay, N. Wales, is for the treatment and care of those of the Upper and Middle Classes suffering from MENTAL AND NERVOUS DISEASES.

The Hospital is governed by a Committee appointed by the TRUSTEES of the Manchester Royal Infirmary. In addition to the Main Building there are separate villas. Extensive grounds. Hard and grass tennis courts, cricket and croquet grounds, and a court for badminton. There are also wireless installations. Golf may be had within easy distance. Occupational therapy.

VOLUNTARY, TEMPORARY, and CERTIFIED PATIENTS received.

The Hospital is nine miles from Manchester, 50 minutes by rail from Liverpool, and 3½ hours from London.

For terms and further particulars apply to the Medical Superintendent, who may be seen in MANCHESTER by APPOINTMENT.

Telephone: GATLEY 2231 (3 lines).

COUNTY COUNCIL OF THE ISLE OF ELY.

ASSISTANT COUNTY MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH (TEMPORARY)

The above Council require the services of a temporary Assistant County Medical Officer, who will also be appointed temporary Medical Officer of Health to the Whittlesey Urban District Council (population 7,971) and to the Thorney Rural District Council (population 2,451).

The duties will include clinical tuberculosis work, and the person appointed will require to have experience of such work.

The salary will be at the rate of £675 per annum, and travelling expenses on the County scale as regards the County Council duties, and £95 plus £5 per annum, and £30 per annum in respect of the Whittlesey and Thorney appointments respectively.

The appointment will be for a minimum period of six months, and the successful applicant will be expected to assume duty as soon after the middle of November as possible.

Applications, together with copies of three recent testimonials, should be sent to the County Medical Officer not later than November 7th, 1938.

Further particulars may be obtained from the County Medical Officer, County Hall, March County Hall.

R F G. THURLOW,

Clerk of the County Council.

October 24th, 1938.

CITY OF MANCHESTER

WITHERINGTON HOSPITAL (1,184 Beds)

(Recognized under the Regulations for the F.R.C.S.)

The Public Health Committee invites applications from registered Medical Practitioners for posts of **THREE RESIDENT ASSISTANT MEDICAL OFFICERS** at the above-named hospital, which will become vacant early in January, 1939.

The salary for each appointment is £200 per annum, with board residence, and laundry in addition, subject to the Manchester Corporation conditions of service.

Each appointment will be made in the first instance for a period of six months, renewable for a further six months but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Town Hall, Manchester, 2, and applications for the posts must be received by him not later than November 10th, 1938.

Town Hall,

Manchester

October 17th, 1938.

R H ADCOCK,

Town Clerk.

CITY AND COUNTY OF NEWCASTLE-UPON-TYNE.

CITY HOSPITAL FOR INFECTIOUS DISEASES.

JUNIOR RESIDENT MEDICAL ASSISTANT (Male)

Applications for the above appointment are invited from duly qualified and registered Medical Practitioners. The holding of a previous resident appointment is essential.

Salary £250 per annum, with board, lodging, etc. The appointment is for a period of one year only. Applications on the prescribed form, which can be obtained on application to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne, 1, must be submitted not later than Saturday, November 12th, 1938.

PHYSIO-THERAPY.—MISS STRONGE, C.S.M.M.G., 41, New Bond St. (May, 2200). Ultra Short-wave diathermy, Bergonié, Foam R.H. baths, Mud, Vav Galvanism, Faradism, Ultra Violet light, Massage, Exercises; at reasonable charges.

CITY OF LEICESTER EDUCATION COMMITTEE

SCHOOL MEDICAL SERVICE.

APPOINTMENT OF EAR, NOSE AND THROAT SURGEON

The Education Committee invite applications from fully qualified medical men or women for the part-time position of Ear, Nose and Throat Surgeon.

Candidates must be specially experienced in this branch of Surgery and must possess the F.R.C.S. Eng., or its equivalent.

Salary will be paid on a sessional basis, viz. — Two sessions a week at the rate of £100 per annum for each session, and additional sessions (average four per week) at £75 per annum for each session. On this basis, which represents approximately the service required but not necessarily guaranteed, the Surgeon appointed would be entitled to a remuneration of £500 per annum, with an agreed supplementary payment (say, £25 per annum) for certain extraneous duties.

The position is not a supernumerary post, and the appointment will be determinable by three months' notice, in writing, on either side.

Application to be made by letter and sent (with copies of three recent testimonials) to the undersigned, from whom further particulars may be obtained, not later than Friday, November 11th, 1938.

Education Department. F. P. ARMITAGE, Director of Education.
Newark Street, Leicester.

October 24th, 1938

COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE

ASSISTANT TUBERCULOSIS OFFICER.

The County Council of the West Riding of Yorkshire invite applications for the appointment of an Assistant Tuberculosis Officer. Candidates must be qualified in accordance with the Regulations of the Minister of Health. The possession of the D.P.H. will be an advantage.

Salary, £500 per annum, rising by annual increments of £25 to £700.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Further particulars and forms of application may be had from the undersigned, to whom all applications, together with copies of not more than three recent testimonials, should be addressed not later than Saturday, November 5th, 1938.

J. CHARLES McGRATH, Clerk of the County Council.

County Hall,

Wakefield

October, 1938

CITY OF BIRMINGHAM.

SEELY OAK HOSPITAL (520 Beds)

JUNIOR MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for the whole-time appointments of Junior Medical Officers (male) at the Seely Oak Hospital, Birmingham.

The appointments will be for periods of six months in the first instance, but may be extended at the end of that time for further periods of not exceeding six months.

Salary at the rate of £200 per annum, and full residential emoluments.

Further particulars may be obtained from the Medical Superintendent at Seely Oak Hospital, to whom applications, stating age, experience and qualifications, with copies of recent testimonials, should be forwarded not later than Wednesday, November 9th, 1938.

The Council House, F. H. C. WILTSHIRE, Birmingham. Town Clerk.
October, 1938.

BOROUGH OF BLYTH. RIVER BLYTH PORT HEALTH AUTHORITY. MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of a full-time Medical Officer of Health School Medical Officer for the above-mentioned Borough and Medical Officer of Health for the above-mentioned Authority with the necessary qualifications as prescribed by the Sanitary Officers' (Outside London) Regulations, 1935, the Local Government Act, 1933, the Public Health Act, 1936, and any other Acts and Regulations made thereunder, at a salary of £800 per annum, rising by four annual increments of £25 to £900 per annum.

The person appointed will be required to carry out the duties prescribed by the said Regulations and Acts and such other duties as may, from time to time, be prescribed by the Minister of Health or assigned by the Council or authority to the officer.

The successful candidate will be required to reside in the Borough, and the appointment is also subject to the other usual terms and conditions adopted by the Council.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Forms of application may be obtained on application to the undersigned, and completed applications should be endorsed "Medical Officer of Health," accompanied by copies of not more than two recent testimonials, which must be sent to the undersigned not later than November 15th, 1938. Canvassing, either directly or indirectly, will be deemed a disqualification.

Municipal Buildings, J. LEIGH TURNER,
Blyth Town Clerk.

IMPERIAL BUREAU OF ANIMAL NUTRITION, ROWLET RESEARCH INSTITUTE, ABERDEEN.

Applications are invited for the post of DEPUTY DIRECTOR of the Imperial Bureau of Animal Nutrition, which is centred at the Rowlet Research Institute, Bucksburn, Aberdeen, Scotland.

The work of the Bureau consists mainly in the collection and collation of scientific information on nutrition (human and animal) and its dissemination to research workers in countries of the British Commonwealth and abroad.

Applicants should possess an honours degree in Science or a degree in Human or Veterinary Medicine. They should have experience in research on nutrition. A knowledge of foreign languages is desirable and overseas experience will be an advantage.

The salary scale is £400-£20-£600-£25-£800.

The initial salary within the scale will depend on the qualifications and experience of the person appointed. For a properly qualified applicant early promotion to the £600 level is probable.

The person appointed will be included in the Federated Superannuation Scheme for Universities after one year's probation.

Applicants should state age, experience, and qualifications and give at least two testimonials or references.

Applications should be addressed on or before November 19th to:-

SIR DAVID CHADWICK,

The Secretary,

Imperial Agricultural Bureau

Queen Anne's Gate Buildings,

London, S.W. 1

COUNTY BOROUGH OF BRIGHTON. BRIGHTON MUNICIPAL HOSPITAL.

Applications are invited from duly qualified men for the post of SECOND RESIDENT ASSISTANT MEDICAL OFFICER at the Brighton Municipal Hospital.

Candidates must be single men, and preference will be given to those holding an F.R.C.S. or who produce evidence of having had practical surgical experience in a recognized hospital, as the appointment is primarily for surgical work, although not exclusively so.

The appointment is for one year, but the person appointed will be eligible for appointment for a further year.

Salary £175 per annum together with residential allowances valued for the purposes of superannuation at £150 per annum.

Forms of application, conditions of appointment, and list of duties may be obtained from the undersigned, which forms, duly completed and accompanied by copies of testimonials, must be returned to the Medical Superintendent not later than Wednesday, November 16th, 1938.

Canvassing the Committee, either personally or by letter, will be considered a disqualification for appointment.

HULL CORPORATION HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH
(for Port Health Work).

Applications are invited from duly qualified medical men, under the age of 40 years and of not less than three years' standing in their profession, for the appointment of Assistant Medical Officer of Health.

Salary £400 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700. Candidates must hold a registered degree or diploma in State Medicine or Public Health. Experience in Port Health Work and Infectious Diseases will be considered special qualifications.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Thursday, November 3rd, 1938.

NICOLAS GEBBIE, M.D.,
Medical Officer of Health.

Health Department,
Guildhall, Hull,
October, 1938.

HULL CORPORATION HEALTH DEPARTMENT.

CONSULTANT OBSTETRICIAN AND
GYNAECOLOGIST.

Applications are invited from registered Medical Practitioners for the appointment of Consultant Obstetrician and Gynaecologist (part-time) to the Corporation's Hospitals, Institutions, Clinics, etc.

Candidates must be Fellows of one of the Royal Colleges of Surgeons and Members or Fellows of the British College of Obstetricians.

The successful candidate will be permitted to undertake private consulting practice, but general medical practice will not be allowed.

Salary £700 per annum—appointment non-resident.

Applications on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Monday November 7th, 1938.

NICOLAS GEBBIE, M.D.,
Medical Officer of Health.

Health Department,
Guildhall, Hull,
October, 1938

BOROUGH OF HORNSEY. WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified Medical Women (married or unmarried) for the appointment of an Assistant Medical Officer of Health and School Medical Officer.

The duties are chiefly those of the Maternity and Child Welfare and School Medical Departments and include refraction work and the treatment of eye conditions in children.

The salary is £600 per annum, rising; subject to satisfactory service, by annual increments of £25 to £700. The appointment will be subject to the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on special forms to be obtained from the Medical Officer of Health, Town Hall, N.8, should be filled in and returned to the undersigned not later than Saturday, November 19th.

Testimonials are not required in the first instance. Candidates selected for interview will be required to send copies of three testimonials at a later date.

Town Hall, H. BEDALE,
Crouch End, N.8. Town Clerk.
October 27th, 1938.

BOROUGH OF JARROW. ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified and registered medical practitioners for the above appointment. The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act of 1922, and the successful candidate will be required to pass the necessary medical examination.

The duties of the post include work in connexion with the School Medical and Maternity and Child Welfare Services, and such other duties as may be required by the Council. Conditions of employment and duties are attached to application forms.

Applications, which must be in the form obtainable from the Medical Officer of Health, Town Hall, Jarrow, should be addressed to the undersigned, endorsed "ASSISTANT M.O.H." and delivered not later than November 9th, 1938.

Town Hall, CHARLES S. PERKINS,
Jarrow Town Clerk.

STAFFORDSHIRE COUNTY COUNCIL. STANDON HALL ORTHOPAEDIC HOSPITAL. (120 Beds.)

HOUSE SURGEON (Female).

Applications are invited for the post of House Surgeon (female) at the above Hospital at a salary of £200 per annum, with full board and lodging. The appointment is for one year and is not renewable. A month's holiday is allowed during the term of service.

Applications, stating age and qualifications, accompanied by three recent testimonials, must be delivered to the undersigned not later than November 10th, 1938. Candidates receiving a reply by November 26th, 1938, may assume the vacancy filled.

County Buildings, H. L. UNDERWOOD,
Stafford Clerk of the County Council.
October 24th, 1938.

COUNTY BOROUGH OF SUNDERLAND CHERRY KNOWLE HOSPITAL FOR MENTAL AND NERVOUS DISORDERS

HOUSE PHYSICIAN.

Applications are invited from registered medical practitioners for the post of House Physician, tenable for one year, at a salary of £200 per annum and board residence. No experience, but interest in the work is necessary.

Applications, with fullest particulars and testimonials, to Medical Superintendent, Cherry Knowle, Ryhope, Sunderland, Co. Durham, by November 12th.

COUNTY COUNCIL OF INVERNESS PARISH OF GLENELG (MALLAIG PART)

MEDICAL OFFICER wanted for the Parish of Glenelg (Mallaig Part). Salary in respect of professional appointments £140 per annum, in addition to which an allowance from the Highlands and Islands (Medical Service) Fund will be payable. Rent-free house is provided at Mallaig.

Further particulars may be obtained from the County Clerk, County Buildings, Inverness, with whom applications, accompanied by testimonials, should be lodged not later than November 12th, 1938.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

CITY OF COVENTRY. ASSISTANT MEDICAL OFFICER (Woman).

Applications are invited from duly qualified and registered women Medical Practitioners under 40 years of age for the post of Assistant Medical Officer in the City of Coventry Public Health Department. The duties will be in connexion with the maternity and child welfare scheme. Candidates should possess a Diploma in Public Health, and preference will be given to those having special experience in the conduct of ante-natal clinics.

The salary will be £503 per annum, rising by annual increments of £25 to a maximum of £700. The officer appointed will be required to devote her whole time to the duties of the post.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass the necessary medical examination as to fitness and to contribute to the Superannuation Fund.

Applications, together with copies of three recent testimonials, must be made on the prescribed form (which may be obtained on request) and must reach the undersigned on or before November 3rd, 1938. The Council House, A. MASSEY, M.D., Coventry, Medical Officer of Health.

October 17th, 1938.

BOROUGH OF TOTTENHAM WELFARE AUTHORITY.

MATERNITY AND CHILD WELFARE COMMITTEE.

VISITING ANAESTHETIST.

Applications are invited for the post of Visiting Anaesthetist to the above Authority in connexion with their Dental Scheme for the treatment of expectant mothers and children under 5 years of age.

Remuneration will be at the rate of two and a half guineas per two hours' session and the number of sessions will be one per month to commence with. This number is likely to be increased in the near future.

Preference will be given to applicants holding Hospital Visiting Appointments.

Applications, accompanied by a copy of three recent testimonials, should be forwarded to the Medical Officer of Health, Town Hall, Tottenham, N.15, not later than Tuesday, November 1st.

M. F. DAVIDSON, Clerk to the Committee.
October 13th, 1938.

LANCASHIRE COUNTY COUNCIL. PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL, Aston-under-Lyne, near Manchester

APPOINTMENT OF RESIDENT OBSTETRICAL OFFICER.

Applications are invited for the appointment of Resident Obstetrical Officer at the Lake Hospital, Aston-under-Lyne, near Manchester (300 beds—approximately 600 births per year).

Applicants must hold the Diploma of the College of Obstetrics and Gynaecologists or a Diploma of similar standing, and preference will be given to applicants who have held a responsible appointment at a Maternity Hospital.

The salary is at the rate of £350 per annum, rising by annual increments of £25 to £400 per annum, together with the usual residential emoluments.

The appointment is for a period of one year in the first instance, and may be renewed for a further period of one year.

Forms of application may be obtained from the County Medical Officer of Health, Hospital and Medical Department, County Offices, Preston, to whom all applications, accompanied by copies of recent testimonials, must be forwarded not later than Wednesday, November 9th, 1938.

County Offices, GEORGE ETHERTON, Clerk of the County Council.
Preston.
October 17th, 1938

SWANSEA COUNTY BOROUGH ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite the applications of women Medical Practitioners for the post of Assistant Medical Officer to assist with the medical services of the Corporation.

Special experience in the treatment of venereal diseases of women and children is essential; Resident Hospital, Mental Deficiency, School Medical Service, and Maternity and Child Welfare experience are desirable additional qualifications.

Salary £500, rising by annual increments of £25 to £700. The appointment is subject to the approval of the Ministry of Health and Board of Education.

Applications, on special forms which can be obtained from Dr. Thomas Evans, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than Thursday, November 3rd, 1938.

COUNTY OF LINCOLN—PARTS OF LINDSEY. PUBLIC HEALTH DEPARTMENT.

SENIOR ASSISTANT AND DEPUTY COUNTY AND SCHOOL MEDICAL OFFICER.

The Council invite applications for the above appointment at a salary of £720 per annum, which sum includes emoluments valued at £100, with an allowance for travelling according to the Council's scale.

Applicants should be under 40 years of age and hold a special qualification in State Medicine or the Diploma in Public Health.

Experience in Public Health administration, with a sound knowledge of the modern methods of the diagnosis and treatment of tuberculosis, is essential.

Terms and conditions of appointment, together with application forms, can be obtained from the undersigned. Applications, which must be accompanied by copies of three recent testimonials, should be received not later than Saturday, November 5th, 1938.

W. S. H. CAMPBELL,
County Medical Officer of Health.
Public Health Department,
County Offices, Lincoln.

HEBBURN URBAN DISTRICT COUNCIL MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

The Urban District Council invite applications from fully qualified Medical Practitioners for the whole-time appointment as Medical Officer of Health and School Medical Officer, at a total inclusive annual salary of £500. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The successful applicant will be required to devote the whole of his time to the duties of the appointment and will not be allowed to engage in private practice. Further particulars, together with a form of application, may be obtained from the undersigned.

Applications, accompanied by copies of not more than three recent testimonials, endorsed "Medical Officer of Health" must reach the undersigned not later than November 2nd, 1938.

Conveying the members of the Council in any form will be a disqualification.
Council Offices, ERNEST FOXALL,
Hebburn, Co. Durham. Clerk of the Council.
October 12th, 1938.

METROPOLITAN BOROUGH OF LAMBETH. DEPUTY MEDICAL OFFICER OF HEALTH.

The Lambeth Borough Council invite applications from fully qualified medical practitioners for the appointment of Deputy Medical Officer of Health for the Borough at an inclusive salary of £340 per annum, rising by annual increments of £40 to a maximum of £960 per annum.

Candidates must not be more than forty years of age on November 17th, 1938, and must possess the qualifications prescribed by the Public Health (London) Act, 1936, and the Sanitary Officers Order, 1926. The gentleman appointed will be required to devote the whole of his time to the duties of the office, to contribute to the Council's Superannuation Fund, and to submit himself to the Council's Doctor for examination, the appointment being subject to such Doctor's report being satisfactory. The appointment will also be subject to the approval of the Minister of Health.

Applications, on forms to be obtained from the undersigned, endorsed "Deputy Medical Officer," accompanied by copies of three testimonials of recent date, are to be delivered by noon on Monday, November 21st, 1938.

Canvassing either directly or indirectly, will disqualify a candidate.

Lambeth Town Hall, O. L. ROBERTS,
Brixton Hill, S.W.2 Town Clerk.
October 28th, 1938.

LONDON COUNTY COUNCIL.

MEDICAL PRACTITIONERS (men and women), with lecturing experience, required as LECTURERS for FIRST-AID and HEALTH CLASSES, day and evening Fee 22s. for lecture of one to two hours Forms T. 7/40 from Education Officer (T. 7), County Hall, S.E.1 (stamped addressed foolscap envelope) Canvassing disqualifies

LOWESTOFT AND NORTH SUFFOLK HOSPITAL.

JUNIOR HOUSE SURGEON (male) required. Salary at the rate of £120 per annum, with board, residence, and laundry. Medical and Surgical qualifications required.

Eligible for senior post at £150 per annum after a period of satisfactory service.

Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

CHESHIRE COUNTY MENTAL HOSPITAL, Parkside, Macclesfield.

Applications are invited for the post of THIRD SENIOR ASSISTANT MEDICAL OFFICER. Candidates must have had previous mental hospital experience and must hold a diploma in psychological medicine. Preference will be given to those who have had experience as a house surgeon or physician in a general hospital.

Salary £550 per annum, rising by two annual increments of £25 each to £600, with house (rent and rate free), coal, electric light, laundry, and garden produce, which are valued for superannuation purposes at £100 per annum.

The appointment will be subject to the provisions of the Asylums Officers' Superannuation Act, 1909.

The hospital has a fully equipped laboratory for clinical and research purposes.

Experience in treatment of out-patients and occupational therapy will be an advantage.

Applications, with copies of three testimonials, must be sent to the Medical Superintendent not later than November 9th.

ROYAL FREE HOSPITAL AND LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.

OBSTETRICAL & GYNAECOLOGICAL UNIT

Applications are invited from registered medical practitioners for the following appointments vacant on January 1st, 1939.

SENIOR ASSISTANT, part-time, £350.

SECOND ASSISTANT, full-time, £500.

THIRD ASSISTANT, full-time, £270, with residence.

Applications, accompanied by copies of not more than three testimonials and the names of not more than two persons to whom reference can be made, should reach one of the undersigned, from whom further particulars may be obtained, by the first post on Friday, November 11th, 1938.

Nine copies of all documents must be furnished.

RICHARD T. BARTLEY, Secretary,

Royal Free Hospital, W.C.1.

NANCIE MOLLER, Warden and Secretary,
London (R.F.H.) School of Medicine for Women, W.C.1.

October 25th, 1938.

7. DEATH VACANCY.—LANCS TOWN.—Old-established, producing about £1,200 p.a. Panel 1,070 patients. Suitable house available. Offers invited.
8. MIDLANDS TOWN.—PRACTICE with scope for anyone wishing to combine electrical work with general Practice. Receipts over £1,500 per panel of 1,630 patients. Good house available.
9. S.W. ENGLAND.—PARTNERSHIP.—Up to ONE-THIRD SHARE in old-established good-class Practice averaging over £4,500 p.a. Choice of houses on rental. Premium 2 years' purchase. Incoming partner must be well qualified and interested in medicine.
10. FAVOURITE SOUTH COAST TOWN.—Lock-up PRACTICE producing about £1,250 p.a., of which approximately £1,000 p.a. is derived from panel of 1,699 patients. P.M.S. and club. Surgery on lease at about £82 p.a. inclusive. Purchaser can arrange own private residence.
11. N.E. SEAPORT.—Good mixed PRACTICE established 60 years and producing for last 12 months £2,777. Panel of over 7,500. Several appointments worth about £120 p.a. Central surgery rented at £100 p.a. Suitable for 3 friends in partnership.
12. WELSH COAST.—Old-established PRACTICE producing about £1,950 p.a., including over £425 from panel and about £90 from appointments. Very nice house with ample accommodation. Premium £3,300, or near offer.
13. LONDON, N.W.—Chiefly better-class non-dispensing PRACTICE held by vendor 12 years. Gross cash receipts for last 12 months about £1,800 p.a. Selected panel of 312. Large scope for this work. Fees 5/- to 21/-. Freehold house in very good repair (3 reception, 5 bedrooms, etc.), garden. Price £1,800, part on mortgage. Premium 2 years' purchase.
14. LONDON, S.E.—LOCK-UP PRACTICE.—Sound middle- and working-class PRACTICE producing for last 12 months £1,613. Panel of 2,450. P.M.S. about £10 p.a. Rent of surgery £75 p.a.
15. LONDON, N.W.—PARTNERSHIP SUITABLE FOR MEDICAL MAN OR WOMAN.—A SHARE to produce £1,030 p.a. in very sound mixed-class Practice averaging about £5,100 p.a., including panel of 6,000. Suitable maisonette with 2 reception, 2 bedrooms. Inclusive rent £90 p.a. Premium 2 years' purchase, part payable by instalments, as arranged.
16. LONDON, S.E.—Well-established PRACTICE, chiefly cash. Receipts average about £1,030 p.a., including panel and P.M.S. over £400 p.a. Corner premises with good garage. Premium 1½ years' purchase.
17. SOUTH OF ENGLAND.—HALF SHARE in old-established good mixed-class Practice producing over £3,200 p.a. Panel about 1,500. Appointments worth about £600. Very nice house in good repair. Premium 2 years' purchase. Incoming partner must be experienced, aged about 35-40, preferably have knowledge of anaesthetics.
18. MIDLANDS—COUNTY TOWN.—PARTNERSHIP.—ONE-THIRD or ONE-HALF SHARE in mixed-class Practice having exceptional scope. Gross cash receipts approximately £2,000 p.a., including panel of £1,100 p.a. and P.M.S. £450 p.a. Suitable house rent about £70 p.a. Premium 2 years' purchase.
19. WITHIN 30 MILES OF LONDON.—Very old-established good mixed-class PRACTICE averaging approximately £3,000 p.a., including large panel and valuable appointments. Detached house in own grounds with 2 reception, 5 bedrooms, etc. Can be rented on lease. Good sporting and social amenities. Premium 2 years' purchase.
20. OUTLYING EASTERN SUBURB.—PARTNERSHIP.—ONE-HALF SHARE in exceptionally sound middle- and working-class Practice producing for last 12 months £3,800. Panel of over 4,500. Suitable house with 4 bedrooms, etc. Premium £3,800.
21. RESIDENTIAL TOWN.—PARTNERSHIP.—Practice with ultimate succession is offered in PRACTICE producing approximately £2,000 p.a. Age 35-40. Good house with ample accommodation. Rent £170 p.a., or smaller house or suitable flat available if preferred. Premium £2,800.
22. HANTS.—PARTNERSHIP.—ONE-HALF SHARE in well-established mixed-class Practice producing approximately £2,500 p.a. Panel of 1,350 and appointments worth £273. Fees 3/6 to 21/-. Choice of houses. Premium 2 years' purchase. Incoming partner must be experienced and preferably aged between 35-45.
23. SURREY.—DEVELOPING DISTRICT.—Increasing PRACTICE producing about £650 p.a., including panel of 450. Semi-detached freehold house with 2 reception, 6 bedrooms, etc. Freehold for sale, or smaller house available. Premium 1 year's purchase.
24. LONDON, W.—Better-class non-panel non-dispensing PRACTICE producing between £1,100 and £1,200 p.a. 21/- fees. Large house with ample accommodation. Leasehold for sale, or other premises can be taken. Premium £1,750.
25. S. WALES.—Old-established mainly contract PRACTICE producing last year £2,200, of which £2,050 is from contract and panel. Suitable house available. Future prospects considered excellent, as new works recently erected in district. Premium £3,500, part by instalments.
26. OUTLYING NORTHERN SUBURB.—Very sound PRACTICE in developing area, producing over £2,000 p.a., including panel of about 1,600. Very nice house and garden. Premium 2 years' purchase.
27. SOUTH COAST RESIDENTIAL TOWN.—Upper- and middle-class non-dispensing PRACTICE producing for last 12 months £1,622, including panel of about 900 and appointments worth about £100 p.a. Well situated house near sea with 3 reception, 4-5 bedrooms, large garden, garage. Leasehold for sale. Premium £3,500.
28. DEVELOPING NORTHERN SUBURB.—Rapidly increasing mixed-class PRACTICE on new estate with excellent scope. Gross cash receipts for last 12 months about £1,200. Lowest fee 3/6. Choice of houses. Premium 2 years' purchase.
29. LANCS.—N.W. COAST.—SURGICAL OPENING.—PARTNERSHIP.—ONE-THIRD SHARE (after preliminary assistantship) is offered in old-established practice producing £4,500 p.a. Panel of 1,600. Suitable house available. Premium 2 years' purchase. Incoming partner should be experienced in surgery and preferably hold the fellowship.
30. NORTH OF ENGLAND.—LARGE TOWN.—Well-established chiefly working-class PRACTICE producing £2,250 p.a. Panel of 2,300. P.M.S. £450-£500 p.a. Appointments £100 p.a. Suitable house (2 reception, 4 bedrooms, etc., garden, garage). Price £1,800, part on mortgage. Premium 2 years' purchase.
31. NORTH WALES.—FAVOURITE COAST TOWN.—Better-class non-panel PRACTICE averaging about £900 p.a., and offering good scope. Detached house excellently situated overlooking bay, with ample accommodation. Sport of all kinds and good ead. facilities. Premium £1,400 for quick sale.
32. LONDON, S.E.—PARTNERSHIP.—ONE-HALF SHARE in well-established good mixed PRACTICE, producing approximately £2,600 p.a., including panel of about 1,400. Fees from 1/6. Suitable house available with 5 bedrooms, etc. Premium 2 years' purchase. Incoming partner must be experienced and energetic worker.
33. MANCHESTER.—Very old-established middle- and working-class PRACTICE averaging for last 3 years £1,380 p.a. Panel of £40. Appointments about £180 p.a. Fees from 3/6. House with 3 bedrooms, etc., garden, garage, electric light. Freehold £950. Premium for quick sale, 1½ years' purchase, part by instalments.
34. LONDON, EAST.—Old-established mixed-class PRACTICE averaging about £2,700 p.a., including panel of about 1,300, and increasing. Separate surgery premises. Premium 2 years' purchase.
35. LONDON, N.W.—GROWING RESIDENTIAL DISTRICT.—PARTNERSHIP.—Guaranteed share in rapidly expanding Practice producing to commence about £500 p.a., with increase later. Suitable detached house on rental at £52 p.a. Incoming partner must be experienced and energetic.
36. KENT.—RAPIDLY EXPANDING DISTRICT.—Well-established middle- and working-class PRACTICE producing about £1,700 p.a., including panel of nearly 1,400. Good house with 2 reception, 5 bedrooms, etc., large garden. Inclusive rent £130 p.a. Premium 2 years' purchase.
37. MIDDLESEX.—DEVELOPING AREA.—Well-established mixed-class PRACTICE averaging over £1,000 p.a., including panel of 880 and appointments worth about £100 p.a. Corner house with 2 reception, 4 bedrooms, etc., garden, garage. Rent £100 p.a. Prem. £2,000 or near offer for quick sale.
38. YORKS.—COUNTRY PRACTICE.—Old-established, income about £1,030 p.a., with scope for increase. About £350 of present income is derived from panel of some 500 patients. Good freehold house with ample accommodation, garden and garage. Price for practice and house £3,600 of which about £1,900 may be left on mortgage.
39. GLOS.—NEAR WYE VALLEY.—Very sound PRACTICE producing about £1,300 p.a., including panel of 1,150 patients and appointments worth about £80 p.a. Low expenses. Detached house with large garden, 5 bedrooms, etc. Freehold. Premium £2,200 purchase.
40. FAVOURITE SOUTH COAST RESORT.—Private and better-class PRACTICE averaging over £1,000 p.a. Minimum fee 5/-. No dispensing. Scope for panel if desired. Modernized house with ample accommodation. Premium £1,000.
41. MIDLANDS.—GOOD RESIDENTIAL COUNTRY DISTRICT.—Country PRACTICE in present producing about £750 p.a., but capable of considerable expansion. Choice of 2 houses. Moderate premium for quick sale. Vendor retiring through ill-health.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

ENO'S 'FRUIT SALT'

contains no sulphates

THE value of the sulphonamide drugs in streptococcal—and probably other—infections is now an established fact. But, it is also known that there are certain avoidable dangers attendant on their administration. Perhaps the greatest danger is consequent on the coincident administration of drugs containing sulphur—a combination which is very apt to give rise to sulphaemoglobinaemia. This danger cannot be avoided even by taking very small quantities of the drugs.

Rightly, therefore, it is advised that the ordinary mineral salines, effervescent or otherwise, should not be used in connection with sulphanilamide or any drug in the sulphonamide group. Nearly all these salines contain either sulphate of magnesium (Epsom Salt), or sulphate of sodium (Glauber's Salt), or mixtures of the two, more or less disguised by the addition of sugar and artificial flavourings.

ENO'S 'Fruit Salt,' however, is in a different category, containing no trace of sulphur or sulphate. It is a well-balanced combination of selected alkalis and fruit acids.

'Fruit Salt' is a physiologically sound laxative acting on the natural principle of osmotic diffusion; it is also an effective systemic alkalizer, one teaspoonful being equal in alkalizing value to eight ounces of orange juice.

The words 'Eno' and 'Fruit Salt'

are registered trademarks.

TAVISTOCK SQUARE

A Triumph of Emulsification

THE OILY RING AROUND
THIS DROP TELLS THE STORY.

The ring around the drop tells the story. A drop of Agarol on blotting paper holds firmly together. Try this with a poor emulsion and you will soon see the mineral oil being taken up by the blotting paper, forming a greasy ring around the drop. For dependable efficacy in the treatment of constipation and allied disorders Agarol—mineral oil, agar-agar and

phenolphthalein emulsion—has attained a reputation all its own.

Only the finest and purest ingredients are used in Agarol. Its exceptional palatability, secured without artificial flavouring, renders it acceptable to both children and adults. Agarol contains no alcohol and no alkali and, being devoid of sugar, is particularly suited to diabetic cases.

Agarol

BRAND COMPOUND

FOR CONSTIPATION

Supplied in bottles containing 4½, 7½ and 17 ounces.

Agarol is not advertised to the public.

EXTRACTS FROM PRESS NOTICES

The majority of the reviews have been favourable.

***** Remains as great a book as ever to the busy practitioner and to the harassed student."—*Practitioner*.

**** Even the most critical could reasonably desire no more as regards text, illustrations, and general make-up."—*British Medical Journal*.

*** The teaching is sound and up-to-date."—*The Lancet*.

***** The best of its kind in the English language."—*Medical Press and Circular*.

** An excellent book."—*American Journal of Surgery*.

*** A wealth of illustrations of outstanding excellence offers many interesting features for the German reader."—*Der Chirurg*.

**** One of the most easily readable, assimilable and pleasurable of surgical books."

—*Medical Journal of Australia*.

***** We have no praise high enough for this book."—*South African Medical Journal*.

*** Holds a high place in the list of standard text-books."—*Canadian Medical Journal*.

***** One of the best of all text-books on surgery."—*St. George's Hospital Gazette*.

**** One of the most popular books on surgery of the present day."

—*Middlesex Hospital Journal*.

** Sound and up-to-date."—*Journal of the American Medical Association*.

**** One of the soundest English text-books of surgery."

—*Liverpool Medico-Chirurgical Journal*.

**** A masterpiece of clarity of press and picture."—*Bristol Medico-Chirurgical Journal*.

**** It has won a great and deserved reputation."—*St. Mary's Hospital Gazette*.

**** Is as good a book on the subject as can be bought."

—*St. Bartholomew's Hospital Journal*.

***** A really great book."—*London Hospital Gazette*.

** The authors have successfully eliminated all obsolete methods."

—*British Journal of Surgery*.

***** The best of the short text-books on surgery."—*University College Hospital Magazine*.

*** Crisp and lucid writing. We strongly recommend this book."—*Indian Medical Gazette*.

"The student would be well advised to avoid this book. Like the devil incarnate, its outward appearance is good, but it must inevitably lead to disaster."

—*Guy's Hospital Gazette*.

This is somewhat at variance with the same journal's review of the Second Edition:—

**** The success which attended the first edition of this admirable work may be justifiably predicted for the new and enlarged second edition. The authors have succeeded with a remarkably small compass in giving a clear and succinct account of the major surgical diseases."

** A popular feature in this new edition is the historical footnotes.

EXTRACT FROM PREFACE:

We believe that there is room for a single volume textbook
in which surgical teaching is based on the fundamental
principles of anatomy, physiology and pathology.

Our object has been to provide students and practitioners
with the essentials of modern surgery in as concise a form
as possible, and also to produce a book which will be of
practical use to students studying for the higher examina-
tions. We have attempted to show that in many diseases
the clinical picture follows logically on the pathological
changes, and without entering into detailed controversy
have indicated those lines along which still unsolved
problems should be pursued.

BOOKS

NEW

NEW

BARSKY'S PLASTIC SURGERY

Dr. Barsky deals with plastic surgery problems of the entire body—from head to extremities. No detail upon which success may depend is overlooked. General principles, psychological considerations, pre-operative preparation, anaesthesia, etc., are fully described. The various types of skin grafts and the exact technique of making them are given in detail. The treatment of wounds, burns and frostbite, scars and keloids; the repair and correction of disfigurements and abnormalities of the orbit, nose, ear, lips, cheeks, jaws, facial bones, neck, trunk, and extremities; all are fully discussed. This new book is outstanding in the manner in which it presents a highly important subject.

By ARTHUR JOSEPH BARSKY, M.D., D.D.S., Associate Surgeon in Charge of the Department of Reconstructive Surgery, Beth Israel Hospital, New York City. Octavo of 355 pages, with 770 illustrations on 432 figures. Cloth, 26s. net.

Reimann on Pneumonias

NEW

Dr. Reimann's approach is aetiological and follows to-day's accepted classification of the pneumonias. Throughout the book the author gives full details on causes, incidence, virulence, immunity, predisposing factors, pathogenesis, preventive measures, symptoms, etc. *Diagnosis* is given special attention and includes full details on physical signs and their meaning, on clinical and bacteriological methods, and on typing methods. Important facts are stressed throughout the course of the disease.

Above everything else this *new book* will be valued for the practical up-to-date help it gives on *Treatment*—supportive treatment, diet, treatment of specific conditions such as cough, thoracic pain, abdominal distension, anoxaemia and cyanosis, use of artificial pneumothorax, specific immune serum, chemotherapy, convalescent serum, prevention and treatment of complications, etc.

By HOPKIN A. REIMANN, M.D., Professor of Medicine, Jefferson Medical College. With a foreword by R. S. COLE. Octavo of 381 pages, illustrated. Cloth, 25s. net.

Mallory's Pathological Technique

NEW

Dr. Mallory has divided his book into three sections: General Materials and Histological Methods; Special Histological Methods; and Autopsy Methods. There is an extensive consideration of the circulatory system, blood, bone, marrow, lymph nodes, spleen, respiratory system, excretory system, reproductive system and other organs and systems of special importance, while an entire chapter is devoted to infectious agents. Dr. Mallory has included a 75-page section on *post-mortem technique*. And in addition to all this there is a chapter on preservation of specimens and still another on gross and micro-photography.

By FRANK BURN MALLORY, A.M., M.D., S.D., Consulting Pathologist to the Boston City Hospital. Octavo of 434 pages, illustrated. Cloth, 20s. net.

Beck's Haematological Technique

NEW

This new manual is based on the author's wide laboratory experience and on more than 350,000 laboratory tests. Dr. Beck explains fully the technique of procuring blood specimens, the clotting mechanism, and estimation of haemoglobin. There is an entire section on enumeration of cells and determination of indexes, including especially detailed directions for determining normal standards. The book takes up the study of the cell, devotes 82 pages to special studies used in haematology, and concludes with a section on special blood pathology.

By RIGENA COOK BECK, M.A., M.D., Head of the Department of Bacteriology, William and Mary College Extension. With a Foreword by FRANK W. KONZILMANN, M.D., Professor of Clinical Pathology, Temple University. Octavo of 332 pages, illustrated. Cloth, 18s. net.

CHAPMAN & HALL, LTD.**CHRONIC DISEASES
OF THE ABDOMEN**

A DIAGNOSTIC SYSTEM.

By **C. JENNINGS MARSHALL,**
M.S., M.D. (Lond.), F.R.C.S. (Eng.).

Surgeon, Charing Cross Hospital and Victoria Hospital for Children; Surgical Consultant, L.C.C. and Bromley District Hospital; Examiner in Surgery, London University and Victoria University, Manchester. The problem of chronic abdominal symptoms constitutes one of the most frequent and baffling problems with which the practitioner has to deal. The present volume covers completely the essential features in clinical manifestations, and considerable attention is paid to variations in such manifestations which lead to fallacies and difficulties in diagnoses. The author has given comprehensive consideration to the important question of clinical experience, with reference to symptoms in the trunk.

NORMAL LUNG

GOOD CITY LUNG

SMOKE GETS INTO YOUR LUNGS

These photographs are taken, by permission, from a new booklet, 'Britain's Burning Shame,' published by the National Smoke Abatement Society. In view of the importance of this book copies have made been available free at your Gas Showrooms.

The booklet tells the whole horrible story of domestic smoke and the damage it does, inside and out.

Frightening photographs? Yes. But the facts are frightening too! The dirty air and frequent grimy fogs in big cities are, in their own way, mass murderers. If you study the graph of weekly deaths due to lung-diseases in London with the graph of winter fog-days, you will see that every fog-period is followed by a rise in deaths.

70% of a city's fog and grime come from home chimneys burning smoky fuel. Is your chimney adding to the aerial sewage of England's towns?

Every smoky chimney is contributing to general ill-health

because that kind of smoke gets into the lungs and stays there. It breaks down immunity to infection and disease. Can anything be done about it? Yes. Every time someone decides to do away with an old-fashioned smoke-making fire in his house and burn a smokeless fuel (such as gas or coke), it means an extra minute, perhaps, of sunshine somewhere.

Gas and coke are working miracles to make homes clean inside. Eventually there will be an air fit for children and old people to breathe. Gas and Coke will have helped to bring that miracle to pass.

Where you want warmth quickly for short periods, a gas fire! Choice of many colours. It ventilates a room automatically.

**NO
SMUTS
NO
SMOKE
WITH**

The open coke fire burns without smoke Saves 2d. on the 1s. on your fuel bills. Gas-ignited on top. Very convenient.

GAS AND COKE

The fuel of clean homes and cities

★ The above facts and many others as to the injurious effects of smoke may be found in publications of the National Smoke Abatement Society, Chandos House, Buckingham Gate, London, S.W.1. By joining the Society, which is an independent body, you will keep up to date and help the campaign for cleaner cities.

Chapter 1 from BACK TO ACTIVITY*

The necessity for well-fitting sockets

This illustration from "BACK TO ACTIVITY" shows clearly the ill-effects of a badly-fitted socket. Note the excessive roll of flesh, throwing the limbs out of alignment.

A well-fitted socket, enclosing all the flesh and giving a proper seating on the tuberosity of the ischium. Note the good alignment of the socket with the body.

*The subject of stump preparation and limb fitting forms one of the most interesting chapters of Mr. E. R. Desoutter's new "BACK TO ACTIVITY." Dealing with above-knee amputations, Mr. E. R. Desoutter shows how the stump can be most successfully fitted by a triangular-shaped socket which provides a definite bearing point for the tuberosity of the ischium without impeding circulation or the free movement of the muscles. A copy will be sent on request.

The TERRY CEILING MODEL

Anglepoise
LAMP

As good as a second right hand in the surgery

Yet another tremendous advance in surgery examination lamps—the Ceiling Model Terry Anglepoise. Out of the way, yet instantly to hand at a touch, pouring its strong, penetrating, concentrated beam right on to the spot, without any distracting glare in the user's eyes. Will practically reach to any part of the average surgery, thus avoiding awkward light-shifting when the patient must not be moved. Leaves both hands free. A perfect examining and dressing lamp. For sheer efficiency and convenience nothing can simply approach the ANGLEPOISE—adjustable to 1,001 positions at a finger touch—and poised at any angle. Simply marvellous for all "close" work as it throws the clear light necessary for extreme accuracy. It can be brought as close as required. Saves on light bills—a 25 watt bulb works like a 60! Scientifically built—every part superlatively made. Chromium plated arms, tireless springs—for perfect balance. In several models. Models for fixing to wall or table, and on smooth-running castors. "A Triumph for Terry Springs." Prices from 50/- (U.K. only). Patented at Home and Abroad.

NOTE THE ANGLES

BETTER CLINICALLY— and a BETTER INVESTMENT

SIMPLE—

self-starting, burner lights when switch is closed.

SPEEDY—

takes less time to "build up".

FLEXIBLE—

lighter in weight. Mobility is increased. Easier to operate.

LOW-PRICED—

well within the purchasing power of all physicians.

NO need to discuss with you ultraviolet's therapeutic advantages; you *know* what this beneficial radiation accomplishes in treatment of many conditions which you meet daily—rickets, erysipelas, varicose ulcers, secondary anaemia.

You *know* too that ownership of a dependable, efficient, ultraviolet lamp would be a worthwhile investment if such a lamp was purchased at a fair price and on reasonable terms. There is such an apparatus—an entirely new product. It is the VICTOR Model "F" Quartz-Mercury Lamp, lower in price but *better* in every way; better from the viewpoint of both physician and patient. Certainly it merits *your* consideration.

Won't you post the handy coupon—today? You will learn from interesting booklets, which we'll send, what a splendid lamp this is, and how much it would mean to you to own it.

RAYNER'S LEMBAR

Made from finest fresh lemons, good Scotch barley and Glucose (with cane sugar). More efficient, better flavour and more economical than ordinary lemon and barley. *A bottle makes a gallon.* It keeps indefinitely.

SAMPLE sent with pleasure, also useful booklet with special diet sheets and sickroom recipes from a London Hospital. Write to Rayner & Co., Ltd., Medical Dept. B, London, N.18.

2/- a bottle at all leading chemists and grocers.

When the success of a plan depends upon its perfect execution there must be strict co-ordination between the individuals involved. No programme of treatment can relieve the incidence of constipation unless the patient is willing to co-ordinate his efforts with those of the physician. That is why so many doctors prescribe 'Petrolagar' for their patients.

Its pleasant taste and gentle consistent action are acceptable to the patient as well as to the physician. Four types of 'Petrolagar' provide a choice of medication to suit the individual case.

'Petrolagar' is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar-agar.

A VALUABLE, DOUBLE-ACTION ANTISEPTIC *

Local treatment with Sphagnol Peat Ointment gives rapid relief in the most obstinate cases of psoriasis, haemorrhoids, eczema and skin eruptions. The reason is that Sphagnol has a twofold action. First of all it soothes and allays irritation and burning sensations; secondly, the natural antiseptic properties of the peat distillates assist in general treatment. Sphagnol

has proved beneficial over and over again where persistent resistance has been encountered.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.17, 21, Bush Lane, London, E.C.4.

For your attention—A NEW NATURAL FRUIT JUICE

If your patients would like a new fruit juice in their diet, you can safely recommend Dole Pineapple Juice, the pure, unsweetened juice of luscious Hawaiian Pineapples. Besides being a delicious, refreshing drink it is a good source of vitamins A, B and C and natural fruit sugars. The typical analysis below shows you what

Dole Pineapple Juice is composed of:

TYPICAL ANALYSIS

Moisture	85.3%	Crude fibre	0.02%
Ash	0.4%	Titratable acidity as citric acid	0.9 %
Fat (ether extract)	0.3%	Reducing sugars as invert sugar	12.4 %
Protein (N x 6.25)	0.3%	Carbohydrates other than sugars (by difference)	0.38%

If you would like to taste this tangy drink, we will be pleased to send you a sample tin on receipt of your name and address.

2000 doctors have already availed themselves of this offer. Pure . . . unsweetened . . . packed by the exclusive Dole Fast-Seal Vacuum-Packing Process.

Dole Pineapple Juice comes from Hawaii and is the juice of sun-ripened Pineapples.

PROPHYLAXIS OF COMMON

WINTER RESPIRATORY

INFECTIONS

Antiseptic gargles and sprays have an important place in the prevention of colds, tonsillitis and other winter ailments. But, for optimum efficiency, the antiseptic used must have certain "plus" features, in addition to high bactericidal properties. T.C.P. is an ideal antiseptic for this purpose, because it has so many of these "plus" characteristics. Chief among them are *stability*—the maintenance of germicidal efficiency in the presence of organic matter, saliva, blood, pus, etc.; *safety*—T.C.P. is neither irritant nor caustic; *penetrative power*—for the relief of congestion and the stimulation of capillary circulation and phagocytosis; and *analgesic action*—invaluable in painful throat conditions.

ASSIMILABLE IRON

Ovoferrin Brand Colloidal Iron Tonic is known to many physicians as the "children's iron", to others it is the iron of choice in pregnancy. Many physicians find it to be the only form of iron which is simple enough, assimilable enough and agreeable enough for long term feeding. Ovoferrin is tasteless, odourless, non-astringent; it will not stain the teeth; it will not irritate or constipate. Contains no sugar.

OVALTINE

IN SICKNESS AND CONVALESCENCE

THE impairment of digestive powers which is commonly met with in the feverish patient, combined with the lack of desire for food, often aggravates the difficulty of adequately replacing the increased loss of energy and destruction of tissue which occur.

"Ovaltine" provides a satisfactory solution to the problem of alimentation in many cases of sickness and in the stage of convalescence after severe, prolonged and debilitating illnesses, where an easily assimilable, palatable and concentrated nutrient is required. It is always acceptable.

"Ovaltine" replaces with advantage the ordinary milk preparations which so often prove distasteful to the invalid. Prepared from full-cream milk, eggs and malt extract in carefully balanced proportions, it provides complete nourishment in the most readily assimilable form.

A liberal supply for clinical trial sent free on request.

Ergoapiol (Smith)

A Menstrual Regulator...

When the periods are irregular, due to constitutional causes, ERGOAPIOL (Smith) is a reliable prescription. Containing apiol (M.H.S. special) together with ergot, aloin and oil of saffron of the highest quality, this preparation effectively stimulates uterine tone and controls menstrual and postpartum bleeding.

In cases of Amenorrhea, Dysmenorrhea, Menorrhagia and Metrorrhagia, Ergoapiol serves

as a good uterine tonic and hemostatic. Valuable in obstetrics after delivery of the child and for the menstrual irregularity of the Menopause.

Prescribe 1 to 2 capsules 3 or 4 times daily. Supplied only in packages of 20 capsules. Literature on request.

As a safeguard against imposition the letters MHS are embossed on the inner surface of each capsule, visible only when the capsule is cut in half at seam as shown.

Biliary extract	-	0.10	"
Lactic ferments	-	0.05	"
Agar-agar	-	0.05	"
Fiat tablet	-	0.35	"

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

EARLY VEGETABLE DIET

for

OPTIMUM NUTRITION OF INFANTS

It is now widely admitted that vegetable foods should supplement the milk diet of infants as early as possible. The difficulty in prescribing these foods at an early age has however hitherto been the fact that the weak digestions of infants cannot successfully deal with the fibrous cellular tissue, which therefore causes intestinal irritation and consequent upset, frequently manifested by diarrhoea.

The Libby method of Homogenization disintegrates this tough, indigestible cellular fibre, thus enabling it to be easily eliminated, the 'bulk' however being in no way affected. This breaking down of the fibrous walls also has the advantage of enabling the full nutriment to be thoroughly assimilated.

Libby's Homogenized Vegetable Foods for infants are prepared in six scientifically formulated combinations of Cereal, Vegetables and Fruit. These can be prescribed as needed to provide the necessary balance of Vitamins, Minerals and other essentials.

The accompanying table shows the comparative results of carefully controlled experiments with supplementary vegetable diet.

AVERAGE TOTAL INCREASES IN HEMOGLOBIN AND ERYTHROCYTES AFTER SUPPLEMENTING THE MILK DIET WITH HOMOGENIZED VEGETABLES OR STRAINED VEGETABLES		
	Per Cent Increase Above Anæmia Level	
	Hemoglobin	Red Blood Cells
Specially Homogenized Vegetables (carrots, spinach, peas)	89	117
Commercially Strained Vegetables (carrots, spinach, peas)	76	84
Home Strained Vegetables (carrots, spinach, peas)	80	95

Samples together with clinical data and laboratory reports will be gladly supplied upon request to Messrs. Libby, McNeill & Libby, Ltd., 15, Lime Street, London, E.C.3.

INDICATIONS FOR 'SANATOGEN'.

No. 7

ARTERIO-SCLEROSIS and HYPERTENSION

"Room for Scepticism"

There is room for scepticism as to the causative relation between the stress and rush of modern life and high blood-pressure.

Examination of mummies has shown that arterio-sclerosis was common even in ancient Egypt, and it was recently pointed out in a medical journal that "the active goat and the horse have little arterio-sclerosis, while the placid cow and the phlegmatic duck are especially susceptible".

That food-intake is important both in the prevention and in the treatment of hypertension is, however, generally agreed. Purins, toxins and excessive food residues in the colon are all to be suspected and avoided.

In the dietetic treatment of high blood-pressure, 'Sanatogen', a carbohydrate-free product of 95 per cent. pure milk casein *with* 5 per cent. sodium glycerophosphate, has been found of great service. Its nutritive value is high.

BLOOD PRESSURE

"I have been very interested in the effects produced by 'Sanatogen' in a case of high blood-pressure. The patient, a young woman, was put on a restricted diet for high blood-pressure, and used to find that in the middle of the morning and after putting her little boy to bed, she had a feeling of extreme weakness and was often forced to sit or lie down for some time before she could do anything else. She started taking 'Sanatogen' twice a day, and after a short period noticed that this feeling was not making its appearance, and she has never had it again as she is still continuing with the 'Sanatogen'. She is also very much improved in health, and seems to have much more reserve energy now. The only alteration in diet has been the addition of 'Sanatogen'."

—M.B., C.B.

NO TOXINS · NO PURINS · NO RESIDUE

VOLPAR

Volpar is the new contraceptive which has been formulated in co-operation with the medical Sub-Committee of The National Birth Control Association; it is the outcome of nearly ten years' continuous investigation conducted by University research workers under the direction of the Birth Control Investigation Committee.

Laboratory tests have shown that the active principle of Volpar is the most powerful non-toxic spermicidal substance known.

An article reporting the results of the above-mentioned investigation was published in *The Lancet* of October 15th, 1938, p. 882, and a letter signed by the medical members of the Birth Control Investigation Committee commenting upon this article has also appeared (*Lancet*, October 22nd, 1938, p. 970).

Volpar is issued in two forms:—

VOLPAR GELS

Soluble suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath.

VOLPAR PASTE

A non-greasy paste for lubrication of occlusive caps and sheaths or condoms.

Volpar Gels and Volpar Paste are sold only by pharmacists at the following prices (applicable to Great Britain only):

GELS: in screw-capped glass tubes containing 1 dozen gels, 2s. 0d.

PASTE: in collapsible tubes containing sufficient for 12 applications, 2s. 0d.

Head off the secondary complications!

STREPTOCOCCUS ANTITOXIN (SCARLATINA)

LOBULIN **Lederle** MODIFIED

WE collected the experience of 18 hospitals and found, as we expected, that our Globulin-Modified process of refinement had cut in half the percentage of reactions. The percentage of *sum* reactions was only 2%!

We also found in our hands new evidence of the efficacy of antitoxin in heading off sequelae, if administered *early*.

Irrespective of the apparent severity of the case, patients treated on the first or second day of the disease, in most instances, showed a prompt cessation of all symptoms within a few days. When treatment was delayed beyond this period, there was a sharp rise in the incidence of secondary complications and their severity.

Number of Cases	132	97	22
Antitoxin given on	1st and 2nd days	3rd and 4th days	After 4th day
Adenitis	3.7%	7.2%	4.5%
Otitis media	6.1%	8.2%	18.1%
Mastoiditis	..	1.03%	13.6%
Nephritis	..	1.03%	4.5%
Sinusitis	..	2.0%	..

For maximum clinical response, institute antitoxin therapy early and in adequate dosage.

The coming of the Globulin-Modified antitoxin largely relieves the physician from the old fears of reactions and clears the way for the use of the ideal therapy, even in the mildest cases, reducing the incidence of secondary complications.

CRUNCHY FOODS *and health*

Most physicians agree that the soft foods of the modern diet endanger the perfect functioning of the digestive system, and that crunchy foods should have their place in everyone's diet.

The necessity for masticating crisp foods induces a more abundant flow of saliva, and this is generally held to facilitate the work of the digestive tract. Crunchy foods are therefore not only easier to digest in themselves; they also assist in the digestion of the softer foods eaten in conjunction with them.

Crunchy foods eaten regularly have also this advantage: they tend to induce the habit of proper mastication, so that soft food also will be more thoroughly chewed.

Ryvita is a dry, crisp food now frequently recommended by practitioners to their patients. Its consistency makes complete mastication a necessity, and it can be eaten with every meal. A complimentary carton of Ryvita will gladly be supplied on request.

WEANING TIME

From the age of six months, Robinson's 'Patent' Groats and milk is an ideal weaning diet. It is easily assimilated and the slightly laxative properties of the Groats counteract any constipating effects of the milk. Moreover, Groats has the highest fat content of all cereals and is rich in protein. Carbohydrate is supplied in 'Patent' Groats in a form which helps to prevent diarrhoea and vomiting. Baby's digestion is gradually prepared for more solid foods, and bone and muscle are developed at a critical growing stage.

ROBINSON'S "PATENT" GROATS

Descriptive pamphlet and a trial sample will be sent free on application.

SOME NUTRITIONAL PROBLEMS OF CHILDHOOD*

BY

LEONARD G. PARSONS, M.D., F.R.C.P.

Professor of Children's Diseases in the University of Birmingham; Physician to the Children's Hospital and the United Hospital, Birmingham

It is within the discretion of the Trustees of the Dawson Williams Prize to ask the recipient to deliver a lecture on the subject of his researches, and since this is the first occasion on which they have exercised that discretion, it is surely fitting that I should pay homage to the memory of Sir Dawson Williams.

Dawson Williams achieved outstanding success in two spheres of medicine: first, as a paediatrician; and, secondly, as a medical editor. He edited the *British Medical Journal* for thirty years and won for it a position in the forefront of medical literature, and both it and the *Archives of Disease in Childhood*, of which he was one of the sponsors, are abiding memorials to his name. He was a great man physically and intellectually, and withal somewhat of an autocrat, as all who knew him will bear witness. The last sentence he ever wrote for publication was, "Its motto might be 'Thorough,'" and such certainly was his own motto. When he retired from the editorship of the *Journal* it was felt that his work should be commemorated by some form of testimonial, and he, true to his first love, wished that this should take the shape of a scholarship or prize for research in paediatrics. Unfortunately, before the testimonial could take form he died, and later the Dawson Williams prize in paediatrics, open to the British Empire, was founded in his memory. It is to this man that I pay in this lecture an inadequate but sincere tribute.

I wish also to express my thanks for the great honour conferred upon me by the award of this prize; an honour which gives me the greater pleasure in that I follow in the footsteps of my two distinguished teachers, Dr. F. J. Poynton and Sir Frederic Still.

In looking back over my work I find it difficult to choose a comprehensive title for the problems investigated, but since the majority have been associated with some disturbance of nutrition the title "Some Nutritional Problems of Childhood" will cover what I wish to say. I propose to use coeliac disease as a text, because the investigation of that condition has led to a consideration of many other deficiency disorders of childhood. In a paper of this nature it is obviously difficult to keep out "I." In some places "We" has been substituted, and in others the name of a colleague, because I have been assisted by an enthusiastic band of workers who have combined first-class executive and clinical ability with a high degree

of critical and constructive reasoning. My thanks are also due to the Medical Research Council for the generous help which they extended to me for many years.

Beginning my study of coeliac disease with the assumption that deficient absorption of fat was the key to its symptomatology, I now realize that its diverse symptoms are due to impaired absorption of many factors in the diet which are necessary for normal nutrition. At different times the subjects of coeliac disease show symptoms of all the well-known deficiency diseases, as, for instance, rickets, tetany, cataract, scurvy, night blindness, pyoderma, xerophthalmia, atrophic tongue, beriberi, microcytic and macrocytic anaemia, dental hypoplasia, stunting of growth—manifestations which Minot has called "conditioned deficiency diseases."

Coeliac Rickets

Diets severely restricted in their fat content have been used in the treatment of coeliac disease for many years, and although I observed the occurrence of rickets in coeliac disease in 1913, I did not connect its appearance with the diet until it was forcibly brought home to me ten years later by the following case:

In 1919 a girl aged 5 years was found to have coeliac disease and was given a fat-free diet with considerable benefit, but in 1921 she experienced the first of several attacks of tetany, and in 1922 developed knock-knee, which increased so rapidly that a year later walking became impossible. These symptoms were regarded as due to rickets, a diagnosis that was confirmed by radiographs. I was thus placed in the extraordinary position of having, by my treatment, improved one but produced another even more crippling disease; furthermore, if the treatment were continued, it seemed impossible to cure the rickets. Fortunately at this time ultra-violet irradiation was beginning to be widely used in the treatment of rickets; therefore in March, 1925, this form of treatment was started, and nine months later the child who had been bed-ridden for three years was once more able to walk.

Since then we have successfully treated coeliac-rickets by other methods—for example, irradiated cholesterol dissolved in paraffin, irradiated cholesterol in powder form, irradiated ergosterol and calciferol in tablet form dissolved in as little fat as possible and usually given in large doses. We have found that by employing such treatment as a routine in coeliac disease both tetany and rickets can be prevented; otherwise rickets is apt to occur at the growing periods and when the dietic treatment of coeliac disease has produced a resumption of

* The Dawson Williams Memorial Lecture, delivered in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Plymouth, 1938.

growth, for, although osteoporosis may be present, rickets cannot develop unless the child is growing.

An observation made on one of these early cases of coeliac rickets is interesting in connexion with more recent investigations. This observation was the ineffectiveness of sunlight in the Birmingham area to cure rickets. The child to whom I refer was, when first seen, so black from exposure to the summer sun that he looked like an Ethiopian, yet there was clinical and radiological evidence of the most extreme and severe rickets without the slightest sign of healing. The inadequacy of Birmingham sunshine has been demonstrated by a series of experiments in which three groups of rats were given a rickets-producing diet for a period of four weeks: one group was kept in the dark; another exposed daily from 11 a.m. to 1 p.m. (Greenwich mean time) to the open sky, but not the direct sunshine; and the third group exposed for the same time to whatever direct sunshine was available. Brown and Tisdall found that when rachitic rats were thus exposed to direct sunshine healing should become obvious when the sun is about 35 degrees above the horizon, which, in Birmingham, occurs for about twenty-eight weeks in the year. In the first year the rats were exposed in the centre of Birmingham. In spite of the fact that the summer was hot and sunny, healing only occurred in the "sunshine" rats over a period of seventeen weeks and in the "skyshine" rats for a period of nine weeks. It was thought that this limitation in the healing powers of the sunshine and skyshine was due to the considerable smoke pall which hangs over Birmingham, and therefore in the following year we exposed a series of rats in the country on the north-east side of Birmingham about ten miles from the centre of the city, and another series in the centre of the city, and were amazed to find that healing in Birmingham was better than in the country. Therefore, during a third summer three series of rats were exposed; one in the country to the south-west and some seven miles from the centre of the city; one in Birmingham itself; and one in the same situation on the north-east side of Birmingham as in the last experiment. The results showed that healing was slightly better on the south side than in Birmingham and considerably better in Birmingham than in the country on the north-east side of the city. The explanation of these facts is, we believe, that the prevailing south-west winds carry the smoke from Birmingham and the surrounding Black Country to the north-east of Birmingham and that this cuts off much of the curative ultra-violet rays. The child to whom I have referred had been an in-patient at a country hospital situated ten miles to the east of the city centre, and subject to the same smoke drift.

Some deficiency symptoms appear more commonly than others in coeliac disease: for instance, rickets and tetany occur more often than xerophthalmia, scurvy, and beriberi. Again, microcytic anaemia is the commonest deficiency symptom, whereas megalocytic anaemia is one of the rarest. The explanation of these vagaries cannot be the inability of the coeliac child to absorb fat, because xerophthalmia is rare, and scurvy and beriberi occur, but it may be that the "threshold level" required for their development is lower with some deficiency symptoms than with others.

Anaemia in Coeliac Disease

Hypochromic microcytic anaemia occurs so often as to constitute a characteristic symptom of coeliac disease. It is an iron-deficiency anaemia, and essentially similar to Wits's anaemia of adults, since hypochlorhydria is also a common finding. In a few cases megalocytic hyper-

chromic anaemia has been found; in one case this was apparently due to the absence of intrinsic factor, in others to the lack of absorption of the haematinic factor, since improvement occurred when the diarrhoeal period was over. This type of anaemia can be cured by giving liver extract orally or parenterally.

In investigating the anaemias of coeliac disease, my colleague, Dr. Smallwood, discovered in three children a condition of microcytosis without anaemia, the cell count being normal and the cells deeply stained. This he thought was probably due to spherocytosis, the cells being thicker and more globular than normal, as in acholuric jaundice. In view of more recent clinical and experimental investigations, however, I would suggest another explanation. During the cure of nutritional anaemia a condition known as Hagen's phenomenon sometimes occurs in which the red cell count rises to six millions or more per c.mm. before the haemoglobin reaches normal figures, but when the haemoglobin does become normal the red cells fall to the normal number. Recently Dr. Cleland has found that sometimes, after the progressive diminution in the red cells which is known to occur in early infancy, the cells increase to more than the normal number, while the haemoglobin still continues to fall—that is, the reverse of Hagen's phenomenon. In our opinion both this and Hagen's phenomenon are manifestations of a mild degree of iron-deficiency anaemia.

We believe that the first change in an iron-deficiency state is an increase in the number of cells but a decrease in their size without any alteration in the percentage of haemoglobin, probably because the available haemoglobin is used to better advantage if a small cell is well filled than if a large cell is relatively less well filled (Smallwood). I think, therefore, that the condition found by Smallwood was a manifestation of this early iron-deficiency anaemia. The experimental evidence on which my explanation is based was obtained by feeding rats on a diet which, although deficient in iron, is not so deficient as to produce a definite nutritional anaemia. Rats fed on such a diet from weaning at the age of 3 weeks until 3 months old showed practically normal growth and did not appear pale or anaemic. Their haemoglobin was 100 per cent., but the red cells showed an increase of about two million cells per c.mm.; moreover, the red cells were smaller than normal. This combination of microcytosis, polycythaemia, and normal haemoglobin can be cured by adding iron and a trace of copper to the diet, thus proving that it is a response to a deficiency of iron.

Carbohydrate and Fat Metabolism in Coeliac Disease

A few years ago we repeated and confirmed the observation of several workers that oral glucose-tolerance tests in coeliac disease gave a flat and low blood-sugar curve. Moreover, we were struck by the similarity of these curves to the low blood-fat curves which we had found in coeliac disease after test meals of fat, and since there was considerable evidence that the latter were due to impaired absorption of fat from the intestine, we concluded that the low blood-sugar curves were also due to poor absorption, and not to an endocrine defect as suggested by other workers.

Defective fat absorption in coeliac disease has been repeatedly demonstrated by balance experiments, but this method cannot be applied to carbohydrates because bacterial fermentation in the intestine splits up carbohydrate, so that the amount unabsorbed cannot be estimated by faecal analysis. Our theory therefore could not be substantiated directly, but my colleague, Wallace P. B.

suggested that the problem might be solved by the comparison of intravenous and oral glucose-tolerance tests. He accordingly began work on those lines, and the results obtained have completely confirmed our view that carbohydrate is badly absorbed in coeliac disease, and have led to valuable advances in treatment. The suggestion that glucose tolerance should be estimated by the intravenous injection of glucose is not an original one, but in the test as devised by Ross the following points are new: the glucose (20 per cent.) is dissolved in normal saline, the amount of glucose being 5 grammes up to a weight of 10 kg., 10 grammes up to 30 kg., 20 grammes for older children; the maximum injection time is two minutes; the blood sugar is estimated directly after injection and at short intervals thereafter—namely, 2, 4, 6, 8, 10, 15, 20, 30, 40, 60 minutes—from an ear-lobe puncture, using only 0.02 c.mm. of blood.

There are certain other important points about the test: first, the child should be, as far as possible, on a normal diet from three to five days before the test; secondly, the test should be done after a night's fasting; thirdly, everything should be done to keep the child free from emotional disturbance, which itself affects the blood sugar. The diet is important because it is now recognized that the glucose tolerance of a healthy individual is directly proportional to, and solely dependent upon, the amount of carbohydrate the diet contains during the few days preceding the test. In the normal individual a low carbohydrate diet leads to impaired glucose tolerance, which is shown by a high and rather slowly falling blood-sugar curve, whether glucose is administered intravenously or orally; whereas a high carbohydrate diet will lead to the opposite effect—an increased glucose tolerance giving a low blood-sugar curve.

According to Thaysen a flat oral curve is one in which the rise from the fasting level is less than 40 mg. per 100 c.cm.; even more important, however, is the absence or great delay in the occurrence of a true peak and the failure of the curve to fall to the fasting level in two and a half hours even after a small rise. The form of an oral curve depends upon two factors: first, the rate at which sugar enters the blood—and this may be impaired as the result of gastric stasis or through failure of absorption; secondly, the rate of its removal from the blood—that is, the tolerance of the individual. In impaired absorption less sugar enters the blood, thus tending to produce a low curve; but because of this carbohydrate deprivation glucose tolerance is impaired, and this tends to produce a high curve. The resultant curve depends, therefore, on the degree and duration of the absorptive disability. A mild degree of impaired absorption, although leading to impaired tolerance, probably allows a considerable part of the test dose to enter and thus produce a high curve; whereas although as absorption gets worse the tolerance does also, the test dose cannot get in to show it. Actually during the early stages of coeliac disease the oral curve rises and then, as the disease develops, falls to the flat curve. This phenomenon was observed in a child whose symptoms when she first came under observation were failure to gain weight and listlessness, at which time a fairly high curve was obtained, whereas six weeks later, when the diagnosis of coeliac disease was obvious, a flat curve was obtained. During recovery exactly the reverse of this process has been found—namely, the replacement of flat curves by curves rising to a higher level, often with a delayed peak—these curves falling later to the normal level. It is not surprising, therefore, that some cases of coeliac disease and abdominal tuberculosis have shown almost normal oral curves, although the intravenous curves

revealed pronounced impairment of tolerance. It is just such variations in absorption which have enabled Ross to make out a strong case for his view that the correct estimation of glucose tolerance can only be made by intravenous blood-sugar curves, since they are concerned with a single factor—the removal of glucose from the blood.

These results, and the fact that in established coeliac disease the combination of low oral and high intravenous curves has always been found, furnish important evidence in favour of our thesis that the absorption of glucose from the bowel is impaired in coeliac disease. Furthermore, if our assumption were really true it would follow that the glucose tolerance and general condition of these children should be improved by the administration of glucose. This in fact has proved to be the case, and I have seen the most remarkable success follow this treatment in the severest exacerbations of coeliac disease.

The problem of carbohydrate absorption has been attacked in another way. It is known that glucose tolerance is directly proportional to the sensitivity to injected insulin; therefore, the fall in blood sugar when estimated every five minutes for half an hour after crystalline insulin is injected intravenously into a fasting person—the so-called insulin depression curve—is less in a normal individual on a low carbohydrate diet than when the individual is on a normal diet. If there is impaired carbohydrate absorption in children suffering from coeliac disease they should therefore show an insulin depression curve similar to that found in a normal individual on a low carbohydrate diet, and this is exactly what they do show.

"Insulin Kinase"

The third phase of these investigations was based upon the assumption that insulin, whether produced in the body or injected, is inert until acted upon by a "kinase," formed, chiefly in the liver, in response to the stimulus of an elevated blood-sugar level. If this assumption is true, kinase would be deficient—either as the result of lack of stimulus consequent upon a low carbohydrate intake, such as we have postulated in coeliac disease and in diets deficient in carbohydrate, or because the liver, possibly as the result of disease, is unable to respond to the stimulus and produce kinase. Attempts were therefore made to see if the glucose tolerance and sensitivity to insulin of children suffering from coeliac disease could be improved by giving liver preparations intravenously or orally. The same results were achieved by both methods, although more rapidly with campolon than with liver by mouth—namely, that the intravenous tolerance curves became normal, an effect which was not due to campolon itself having an insulin-like action. It was therefore clear that the poor absorption of carbohydrate in coeliac disease resulted in a diminished production of something, perhaps "insulin kinase," which is supplied by campolon or liver extract. Campolon was chosen by Ross because it is prepared by simple expression methods, and therefore is more likely than the more purified products to contain the kinase; actually a more purified and concentrated preparation—anahaemin—was found to have little effect on the glucose tolerance, indicating that insulin kinase is not identical with the haematinic factor. Another interesting fact is that although the intravenous curves are rendered normal by treatment with liver, and there is ample clinical evidence of improvement in the general condition of the children, the oral glucose-tolerance curves do not improve. The reason for this improvement cannot therefore be an immediate increase in carbohydrate absorption, but,

according to Ross, it may be due to better utilization of the carbohydrate formed in the body from protein. In view of these findings we now give liver extract as a routine in coeliac disease, and have been convinced of its value, although the results obtained are in no sense dramatic, like those obtained in severe relapses by the intravenous administration of glucose.

It is interesting to note that Minot and his colleagues regard sprue as primarily a deficiency disease closely allied to pernicious anaemia, and believe that in both there is involved a failure of a reaction between an extrinsic factor in the diet and an intrinsic factor present in the gastric juice of a normal person. Moreover, they class coeliac disease and idiopathic steatorrhoea with sprue, and state that those substances in liver extracts which are effective in pernicious anaemia have a highly beneficial effect on the major features of sprue. Recently, Barker and Rhoads have investigated blood-fat curves in sprue after a fat test meal and obtained results similar to those found by us in coeliac disease, but they also found that after the parenteral administration of liver extract the curves approached normal. In one patient a single injection sufficed to produce this change, but in two other cases several daily injections were required—a result which they say suggests that liver extract exerts some specific effect in converting malabsorbing intestines to normal function. Liver treatment does not produce this dramatic effect in coeliac disease, and low blood-fat curves may be found after months of liver treatment. Again, although carbohydrate absorption gradually improves as the child approaches normal health, it does not, as I have shown, improve immediately after, or even in a relatively short time after, the institution of liver treatment; moreover, the factor in liver which improves glucose tolerance in coeliac disease is not the haematinic factor. Coeliac disease is therefore not a conditioned deficiency caused by lack of specific reaction between extrinsic and intrinsic factors, although the megalocytic anaemia of coeliac disease can be cured by the parenteral administration of haematinic factor; furthermore, the results of the American observers, if confirmed, seem to differentiate sprue from coeliac disease.

I have followed Ross in postulating the existence of an insulin kinase produced chiefly in the liver. The theory that insulin requires an activator insulin kinase is due to Himsworth, but, unfortunately, with the help of McNair Scott he has recently proceeded to strangle the infant to which he had given birth. They now suggest that the reduction in carbohydrate tolerance and decreased insulin sensitivity produced by a low carbohydrate diet are better explained by an increased secretion of the anti-insulin substance of the anterior pituitary—that is, by an inhibitor rather than by an activator such as insulin kinase. It is, however, as pointed out in an annotation in the *Lancet*, possible that both inhibitor and activator may exist and that the anterior pituitary extract may act by inhibiting the production of insulin kinase. If an activator of some variety is not present in liver it seems impossible to explain the results which I have described, because Ross has quite convinced me of the accuracy of his observations.

Phosphorylation

There is, however, another interesting and possible explanation of the undoubted improvement brought about by liver extract in coeliac disease. According to Verzár, fat, glucose, galactose, and vitamin B₂ (lactoflavin) are absorbed from the intestine by phosphorylation, a process which, together with dephosphorylation, constitutes a

mechanism for the transport of phosphoric acid from one compound to another. By this process fatty acids are synthesized to phospholipoids and neutral fat in the intestinal mucosa, glucose to a hexose phosphoric acid, and vitamin B₂ to lactoflavin phosphoric acid. Furthermore, the "yellow respiration ferment" of Warburg, which is a combination of lactoflavin phosphoric acid with a specific protein, is probably necessary for phosphorylation to be carried out, and is also the form in which lactoflavin is chiefly absorbed and stored in the liver. If, therefore, phosphorylation does not take place the absorption of fat, glucose, and lactoflavin is greatly impaired, although a certain amount of glucose may be slowly absorbed by diffusion. Verzár maintains that phosphorylation is regulated by adrenal cortical hormone because it does not take place in adrenalectomized animals. Phosphorylation may also be prevented by the administration of monoiodoacetic acid, and young rats chronically poisoned by this acid become stunted in growth and show impaired absorption of fat and glucose from the intestine, a condition which Verzár regards as experimental coeliac disease. He found that this disease in rats could be cured "as effectively as in man" by the administration of yeast or liver, because these substances contain lactoflavin phosphoric acid, and he also found that injection of adrenal cortical hormone into adrenalectomized animals rendered their fat absorption normal. He therefore believes that coeliac disease may result from adrenal cortical insufficiency, and that the administration of liver extract, yeast, or adrenal cortical hormone will cure the condition by rendering fat, glucose, and vitamin B₂ absorption normal.

Now, all our patients suffering from coeliac disease are given liver and marmite (crude yeast extract) as a routine; therefore, if Verzár's theory is accurate and coeliac disease is due entirely to failure of phosphorylation, cure should be as rapid and absorption should be rendered normal as quickly as described by the American workers when patients suffering from sprue are treated with liver. Unfortunately, as I have already stated, our experience in coeliac disease has been that whereas clinical improvement undoubtedly does occur following liver treatment, there is no immediate and dramatic improvement in absorption of fat and glucose; that, moreover, absorption only approaches the normal after months of treatment; and that indeed, even after such a lapse of time, oral blood fat and sugar curves may still be low and flat.

I can therefore sum up by saying that all our work on coeliac disease supports the theory that the symptoms of the disease are the result of defective absorption from the bowel.

Carbohydrate Metabolism in Other Diseases

Observations on carbohydrate metabolism have also been made in many conditions other than coeliac disease; indeed, abdominal tuberculosis has already been referred to. I mentioned a short time ago that, accepting the formation of insulin kinase in the liver, impaired glucose tolerance might be expected to be found in cases of liver disease. This has been observed to be the case in catarrhal and chronic jaundice, cirrhosis of the liver, etc.

The suggestion has been made by J. H. Sheldon that anorexia nervosa is a "functional Simmonds disease—a pituitary black-out of psychological origin," but Ross, in a recent paper, maintained that it could be explained on the ground of starvation. Thus, if for psychological reasons there was a brief abstinence from food, an impaired glucose tolerance would be produced, and the

would lead to a high slowly falling alimentary hyperglycaemia. Now it is known that hunger pains are brought about by injecting insulin and that these are accompanied by gastric contractions of the normal type and an increase of hunger; therefore, hyperglycaemia should lead to failure of hunger and loss of gastric tone. The administration of liver, by improving sugar tolerance, should produce a fall in blood sugar and stimulate appetite, and if, after the appetite is stimulated, a high carbohydrate diet is given, improvement should occur. Treatment on these lines was carried out with great success in a child aged 12, weighing 40 lb. After seven weeks she increased in weight to 67 lb., and her intravenous glucose-tolerance test became normal. We have also used liver extract or campolon for restoring appetite and increasing weight in wasted infants and children. The results have been most encouraging, and almost as dramatic as in the case of anorexia nervosa which I have just described.

Conclusion

There are many other deficiencies of nutrition in coeliac disease, which time does not permit me to deal with, but I thought that an account of the work on liver and carbohydrate metabolism which was inspired by a study of coeliac disease, and of its applications in the treatment of nutritional states, might prove interesting.

A SYSTEM OF RADIUM DOSAGE

BY

H. S. SOUTTAR, Ch.M., F.R.C.S.

Surgeon to the London Hospital

It will be generally admitted that success in the treatment of malignant growths by radium depends upon accuracy of dosage, and that this again depends upon two factors. In the first place the radium must be so arranged that every portion of the region under treatment receives an equal amount of radiation. In the second place the total amount of radium and the time for which this is employed must be such that the total radiation received at each point is adequate for the destruction of the cells forming the tumour.

It is usual and convenient to define the total radiation received in r units, and in general it is found that a radiation of from 6,000 to 7,000 r is sufficient to destroy the cells of a squamous carcinoma. A milligramme of radium screened by 0.5 mm. of platinum may be taken to deliver at a distance of one centimetre a radiation of 8.4 r units per hour. For many reasons it is convenient to make the standard time of treatment 133 hours, or about five and a half days. In this case our one milligramme of radium will have delivered 1,120 r units at a distance of one centimetre. Moreover, there will have been evolved and discharged just 1 millicurie of emanation, so that we can describe our source as 133 mg.-hours, or as 1 millicurie destroyed, whichever is the more convenient. We assume throughout a screenage of 0.5 mm. of platinum. Our calculations are greatly simplified if we accept five and a half days as the standard time of treatment when radium element is employed, as then the number of milligrammes of radium and the number of millicuries destroyed are represented by the same figure. To this fundamental figure, which represents the total energy delivered by our combined sources, we shall apply the term "Index."

The problem before us is so to distribute our sources and to adjust the amount of radium they contain that every portion of the region treated receives a radiation of at least 6,000 r . In general this means the use of complicated charts and most intricate calculations. To avoid this I propose to suggest certain simple rules by which we can reach an approximately accurate solution, setting up certain standard distributions which can be modified to meet the requirements of any special case.

Simple Rules for Calculating Dosage

The two methods of radium treatment in most general use are by plaques and by insertion. Plaques may be constructed of any size in wax or other material on which the radium is supported, and they are generally applied externally. We have, however, recently employed small plaques made of dental wax and inserted temporarily into the tissues. One advantage of a plaque is that the radium can be distributed upon it in an exact manner, so that we can know with great accuracy the effect which will be produced.

In order that this effect should be as uniform as possible over the region of application, the radium must be distributed in a certain manner, and it can be shown that remarkably flat and uniform fields of irradiation are obtained if one-half of the radium is distributed uniformly over the surface of the plaque and one-half around its circumference. Moreover, with this arrangement the intensity falls off roughly as the distance from the plaque, and not as its square.

Assuming such an arrangement, how are the amount of radium required and the time of exposure related to the size of the plaque, or, in other words, what is the Index of the plaque? For circular plaques we suggest the very simple rule that the Index is the diameter of the plaque in millimetres. Plaques so constructed and employed give over a large range almost identical depth doses—that is to say, they form appliances of similar power for the treatment of tumours of different dimensions. Their exact characters will be clear from the accompanying table, from which it will be seen that they form convenient standards requiring only slight modification to meet special circumstances. In most cases plaques are built up by mounting needles or seeds directly on a model of wax or other plastic material, when it will be seen that the rules we have laid down form a very useful guide. Even where the plaque is not circular we have a sufficiently accurate approximation if we take its average diameter as a basis for calculation. Where, however, it is bent upon itself, as, for example, in treating a carcinoma of the alveolar margin or the lip, allowance must obviously be made for the effect of cross-fire.

Table for Calculating Depth Dose

Diameter (Centimetres)	Index	Depth from Active Surface of Plaque in Centimetres					
		0.5	1	2	3	4	5
3	30	24	13.9	6	3.1	1.9	1.3
4	40	21	13.4	6.7	3.8	2.3	1.6
5	50	19	12.8	7	4.2	2.7	1.9
6	60	17.2	12	7	4.5	3	2.1
7	70	15.7	11.2	7	4.6	3.2	2.3
8	80	14.5	10.5	6.7	4.6	3.3	2.5
9	90	13.5	10	6.6	4.6	3.4	2.6
10	100	12.5	9.4	6.4	4.7	3.5	2.7

Depth dose in units of 1,000 r for standard plaques.

Turning now to the methods of insertion, it often happens that what we are really constructing is an inserted plaque, when the above rules still apply. This is the case, for example, in the treatment of carcinoma of the breast, where in effect a plaque is formed on the chest wall, or in the treatment of some cases of secondary glands in the neck. In other cases, however, where we are dealing with a localized tumour it is better to regard the problem from a different aspect.

Suppose that we require to treat a spherical mass of growth and that it is possible to distribute our radium both around it and throughout its substance, how should it be distributed and how much should we employ? Again two very simple rules can be formulated. As regards the distribution, arrange one-quarter of the radium uniformly through the growth, and three-quarters just outside its palpable limits—that is to say, just beyond the growing edge. In this way it can be shown that every point of the growth received a nearly equal dose. As regards amount, the number of milligrammes required for a treatment extending over five and a half days or, what is numerically the same, the number of millicuries destroyed—that is to say, the Index—is given by the square of the diameter of the growth in centimetres.

This simple rule depends upon the physical fact that in the case of a sphere such a distribution gives a very uniform irradiation throughout, and at its centre a total irradiation of exactly 6,720 *r* units, whatever the diameter of the sphere may be. For clinical purposes where a tumour is only roughly spherical we obtain a sufficiently accurate result by taking its average diameter.

Comment

It is not, of course, suggested that the rules we have laid down form an infallible guide to radium dosage, or that they can in any way replace experience or the exact calculations of the expert. It is, however, felt that they form standards which even the expert may use as a starting-point, and which he can readily modify to meet any special requirements. The conception of the Index certainly simplifies calculation, and in effect reduces all our problems to a single scale.

The 1938-9 programme of the West London Medico-Chirurgical Society opened on October 7 with the presidential address by Dr. Maurice Shaw on heredity and medicine. Other meetings have been arranged as follows: Friday, November 4, 8.30 p.m., clinico-pathological meeting at West London Hospital. Friday, December 2, 7.45 p.m., at De Vere Hotel, Kensington, W., Discussion: "Illegal Operations." To be opened by Mr. Cecil Binney, Dr. C. P. Blacker, Mr. Aleck W. Bourne, and Dr. W. J. O'Donovan. Friday, January 13, 7.45 p.m., at De Vere Hotel, Discussion: "Some Aspects of Medical Folklore." To be opened by Dr. J. D. Rolleston. Friday, February 3, 8.30 p.m., clinico-pathological meeting at West London Hospital. Friday, March 3, 7.45 p.m., at De Vere Hotel, Discussion: "Pre- and Post-operative Treatment." To be opened by Dr. E. H. Hudson, Mr. Cecil Joll, and Mr. A. Simpson-Smith. Friday, April 14, 7.45 p.m., at De Vere Hotel, Discussion: "Sex Glands in General Practice." To be opened by Professor E. C. Dodds and Dr. L. P. E. Laurent. Friday, May 5, 7.45 p.m., at De Vere Hotel, Discussion: "Some Recent Advances in Medicine." To be opened by Professor Henry Cohen. The Cavendish Lecture will be delivered at Kensington Town Hall on Wednesday, June 7, at 8.30 p.m., and the annual dinner will be held at the Trocadero Restaurant on Wednesday, July 5, at 7.45 p.m.

THE ANTI-PERNICIOUS PRINCIPLE: SOME EXPERIMENTS WITH URINE

BY

EDOUARD JÉQUIER, M.D.,

Chef de Clinique

AND

G. R. M. APSEY, M.D., D.P.H.

Major, Indian Medical Service

(From the University Medical Clinic, Lausanne, by permission of Professor L. Michaud)

We have no proof that the anti-pernicious principle circulates in the blood, although some authors explain in this manner the partial efficacy of blood transfusions in pernicious anaemia. Its presence in organs other than the liver cannot be deduced from the experiments of Whipple and Robschey-Robbins (1925), which established that the haematopoietic power of the kidneys, for example, is equal to that of the liver, that of the brain one-third as great, etc. The experiments of Whipple were based upon the rate of blood regeneration in dogs exsanguinated by successive haemorrhages, and in no way prove the presence of *anti-pernicious* principle in the organs concerned. It remained for Minot and Murphy to apply clinically the discoveries of Whipple and to show that pernicious anaemia was peculiarly responsive to the action of liver. Furthermore, since the introduction of therapeutic extracts (Cohn, McMeekin, and Minot, 1930) of increasing purity it has become possible to distinguish the specific action due to anti-pernicious principle from that which causes blood regeneration in non-pernicious anaemia and is due to other haematopoietic substances (Farrar and Sturge, 1936; de Jong, 1938).

The presence of an anti-pernicious principle has, however, been demonstrated in the kidneys (McCann, 1923), the lungs (Hitzenberger, 1934), the brain, salivary glands, and pancreas (Dakin, Ungley, and West, 1936), and the saliva (Tempka, 1936). This substance, as emphasized by Wakerlin (1937), cannot be precisely identified with that of the liver, since the methods employed in preparing active extracts of liver are ineffective when applied to other organs.

Briefly, although we are in the realms of hypothesis, it would not appear unlikely that the anti-pernicious principle, widely diffused throughout the body and present in the kidneys, should be eliminated, like so many hormones, in the urine. In 1935 Wakerlin reported favourable results from the treatment of pernicious anaemia by intramuscular injections of a concentrated extract of normal urine, while Decastello (1935) obtained similar results with urine administered both by injection and per rectum. Wakerlin, however, in a more recent work (1936), based upon a greater number of cases, was unable to confirm his previous results.

The confirmation of such a fact as the presence of an active anti-pernicious principle in normal urine would not only possess a considerable theoretical interest—in establishing that the metabolism of the principle is not confined to the alimentary tract and liver—but would have a practical application in suggesting the elaboration of a method of biological diagnosis of pernicious anaemia based upon the absence of anti-pernicious principle from the urine. It is for this reason that the experiments to be described were attempted.

Choice of Method

The fact that pernicious anaemia does not occur in animals greatly limits our means, since animal experiments do not enable us to distinguish between a simple haematopoietic action and a specific anti-pernicious action. Such experiments have been far from valueless, since it was by their means that Whipple succeeded in demonstrating the therapeutic properties of liver; yet the interpretation of their results may lead to errors which can only be avoided by clinical control. Within certain limits, however, they may be employed to supplement the scarcity of cases of pernicious anaemia suitable for subjection to long and complicated investigations. (The difficulties of purely clinical experimentation explain the somewhat slow progress which has attended the study of everything touching upon the anti-pernicious principle.) Various methods have been used for such experiments, all of which consist in observing the action of the substance under investigation either upon anaemia or upon the reticulocyte content of the blood of certain animals: space forbids their enumeration here.

The method chosen in the present instance was that depending upon reticulocyte reaction in the white rat. Introduced by Singer (1932), it has been employed by numerous others (Fleischhacker and Schlesinger, 1935; Kamerling, 1935; Baráth and Fülöp, 1935; Leiner, 1935; Fejgin and Plonskier, 1936; Crosetti, Bajardi, and Margulius, 1937; Levi, 1937; Mark and Hauke, 1937); and, with certain differences of technique as previously described by one of us (Jéquier, 1936), has been in use for the past three years at the Lausanne medical clinic. Its details will not be recapitulated here.

The following table shows the results obtained with normal urines.

No. of Tests	Test Material	Result		
		Positive	Negative	Doubtful
10	Normal urine, untreated ..	7	1	2
10	Normal urine, concentrated* ..	10	-	-
10	Normal urine, heated† ..	10	-	-

* Concentrated to half its volume by evaporation *in vacuo* at laboratory temperature, as the animals appeared insufficiently sensitive to small quantities of urine.

† Heated to boiling point for ten minutes to destroy the thermolabile fraction of the anti-pernicious principle.

Owing to the comparative rarity with which untreated cases of pernicious anaemia are now seen at the clinic it was possible to obtain for experimental purposes only four such cases. All four presented a complete clinical picture with the characteristic triad—typical blood picture, disorder of the alimentary tract (glossitis, gastric acidity, tendency to anorexia and diarrhoea, etc.), and disorder of the nervous system; the latter was especially marked in one case which showed typical pseudo-tabes.

The haematological abnormalities were studied not only in the peripheral blood, which revealed intense hyperchromic anaemia with leucopenia and thrombopenia, but also in the bone marrow obtained by sternal puncture. The latter showed inhibition of cellular maturation with predominance of young forms, of which the greater number were megaloblasts as described by Naegeli (1936). In all four cases the blood state was restored to normal by the administration of liver extract.

In each case, before the inception of treatment, a subcutaneous injection of 3 to 5 c.cm. of urine which had been concentrated to half its volume provoked a positive reticulocyte reaction in the white rat. The details of these

reactions, together with those of reactions obtained with one specimen of normal urine, are set forth in the following table.

Table showing Details of Reactions following Injection of Urine in White Rats

Urine	Number of Reticulocytes per 1,000 Red Cells						
	Before Injection		After Injection				
	Day 1	Day 2	Day 1	Day 2	Day 3	Day 4	Day 5
Normal	11	9	12	27	30		
" concentrated ..	15	13	16	35	19		
" heated	13	11	14	16	14	39	
Pernicious anaemia (Mme W. H.) ..	16	23	22	30	33	25	
"	11	10	25	39	14	13

Pernicious anaemia (Mme P.) ..	7	5	11	31	29		
"	11	13	10	29	35		
Pernicious anaemia (Mme P. A.) ..	5	8	11	23	40		
"	14	16	12	41	30		

Conclusions from the Above Experiments

The urine of untreated cases of pernicious anaemia contains, like normal urine, a substance capable of provoking a reticulocyte reaction in the white rat. It may be assumed that this substance is not the anti-pernicious principle of liver, the presence of which could hardly be conceived in such cases; its existence nevertheless precludes the utilization of the present method as a means of demonstrating the absence of that principle. The results obtained are in contradiction to those of Leiner (1935), who found that untreated cases gave a negative reaction which became positive after specific treatment was instituted.

Although it appears that the positive reactions reported above were due to a substance other than the anti-pernicious principle, the possibility remains that the urine of healthy persons may contain this principle. The proof of such a hypothesis would be at least of interest with regard to the metabolism of the principle, and for this reason the clinical investigation now to be described was made.

Clinical Experiment

This experiment was carried out upon one of the four patients previously mentioned (Mme W. H.).

A daily blood count showed a constant level of between 10 and 15 reticulocytes per 1,000 red cells; there was thus no tendency to spontaneous amelioration. The haemoglobin was 58 per cent., the red cells 1,820,000, and white cells 4,000 per c.mm.

From January 24 to 28, 1938, the patient received, after going to stool, a drop-by-drop rectal infusion of 300 to 500 c.cm. of normal urine, specific gravity above 1020, filtered through paper, coloured with Congo red (one drop per 100 c.cm.) and warmed to body temperature. (Decastello in his experiments decolorized and deodorized the urine by filtration through animal charcoal. As this procedure lowers the specific gravity of the fluid to a considerable degree, it was feared that the principle under investigation might be retained by the filter, and filtration through charcoal was therefore omitted.) The first two infusions were well tolerated, but the ensuing ones provoked colic and diarrhoea. It is therefore probable that the urine was not completely absorbed by the intestine. The addition of tincture of opium did not prevent these manifestations.

A daily estimation of the blood urea did not show any elevation during the experimental period. The reticulocyte count remained between 10 and 16 per 1,000 throughout the ten days following the first infusion. On the last day the haemoglobin was 44 per cent., the red cells numbered 1,450,000, and the white cells 2,800. There was no subjective amelioration, such as can often be observed under liver therapy before any change occurs in the blood picture.

Interpretation

According to Minot and Murphy (1927), if ten days elapse without the appearance of a reticulocyte reaction it can be concluded that the substance given is inactive.

There was no question of a state of aplastic anaemia, since the subsequent injection of liver extract provoked a clear reticulocytosis, rising from 31 per 1,000 on the fourth day to 180 per 1,000 on the seventh, with steady improvement of the anaemia until at the end of two months the patient left the clinic with 87 per cent. haemoglobin, 4,000,000 red cells, and a practically normal blood picture.

The doses of urine given in this case were not less than those employed by Decastello. In fact, the latter obtained reticulocyte reactions with daily infusions of 50 to 150 c.cm. (total dosage, 2,000 c.cm.) and clinical and haematological improvement with larger doses—300 to 500 c.cm. per day to totals ranging from 3,000 and 4,000 c.cm. up to 26,000 c.cm.

Obviously no definite conclusion can be drawn from this single case, and it is unfortunate that a similar trial could not be carried out on the other cases, either because their condition did not admit of delay in instituting treatment of known value or because they manifested the alimentary troubles characteristic of their malady.

Until more amply informed, we incline to the opinion of Wakerlin, who, after first demonstrating, as he believed, the presence of anti-pernicious principle in the urine, concluded in the light of further experiments that it was in fact absent.

Summary

1. Human urine, in health and in untreated pernicious anaemia, contains a substance capable of producing a reticulocyte reaction in the white rat.
2. Normal urine, in the case of pernicious anaemia described, showed no therapeutic activity.

THE EARLY DIAGNOSIS OF SCHIZOPHRENIA

BY

W. MAYER-GROSS, M.D.*

(From the Department of Clinical Research, Maudsley Hospital, University of London)

The recent application of new methods of treatment in schizophrenia (by hypoglycaemia and convulsions) has brought into the foreground the necessity for early diagnosis. Whatever their opinion of the absolute value of these new methods, all workers are agreed that the best results are obtained in early cases.

Many views are held as to the nature of schizophrenia. Some regard it as a distinct disease-entity, others as probably embracing a number of different morbid conditions, still others prefer to look on it as a preformed type of reaction shown at a certain level of cerebral disintegration. However that may be, up to now it can be diagnosed only by psychological means. This may change at any time. Biochemistry may provide us with a specific reaction for the whole or some of the cases we call schizophrenic; so may the study of the brain-waves, or any other method. There is perhaps some hope that even the modern therapeutic experiments may enable us to arrive at a physical method of diagnosis. But at present we still have to do without a "Wassermann" of schizophrenia.

Signs and Symptoms

In psychological medicine we cannot proceed, as in general medicine, by collecting signs and symptoms and fitting them into a sort of jig-saw puzzle. All the symptoms have to be related to the psychological background against which they appear. All the circumstances, even though they appear to be side issues, have to be taken into account, and the symptoms have to be evaluated in relation to the personality of the patient, his upbringing and education, and his present environment. Especial difficulty arises in cases with an insidious onset, slight but definite indications of which are often discovered in schizophrenics preceding the appearance of an acute illness.

The characteristic symptoms may be little marked or may be disguised by secondary features that are really the patient's reaction to morbid changes which may be as yet imperceptible. These insidious and slowly progressing cases are often mistaken for neuroses. It is important that they should not escape the attention of the physician, and that they should not be subjected to a prolonged and useless psychotherapy.

Three-quarters of the cases begin between the ages of 15 and 25. Slight depression, a tendency to oppose the older generation, and hypochondriacal concern about the bodily changes in later puberty are to some extent natural at the earlier age. But if these events are exaggerated and prolonged this may be a first premonitory sign. A well-educated, intellectually precocious youth changes from one profession to another, and seems quite unable to find his vocation in spite of all possible facilities and help provided by his relatives. A shy and seclusive girl exhibits an un-influencible stubbornness in her behaviour towards her friends, gradually losing all contact with her family, and becomes a member of a revolutionary sect or group in which also she is regarded as strange. Others go from doctor to doctor with vague complaints of fatigue and rapid exhaustion under comparatively slight stress, intermit-

* With the support of the Rockefeller Foundation.

general nervousness, etc. They look pale, have a greasy skin and sluggish vasomotor response; otherwise no bodily illness can be found. Or the patient may come to the physician complaining of sexual anomalies, in themselves perhaps usual enough in puberty, but described in a cool objective manner devoid of normal bashfulness or concern. Or prolonged shyness or sexual indifference may give place to an exorbitant self-indulgence, regardless of convention or social standards.

If the disease starts later, ideas of jealousy, well founded or not, may be a first premonitory sign, and are usually reported by the partner. Relatives complain to the doctor of a husband's ruthlessness to his wife and children and his lack of interest in his business. Neighbours find a previously gentle and sociable lady becoming suspicious, quarrelsome, and inaccessible to reasonable argument; she becomes slovenly and avoids any contact until the neglect of her children provokes the attention of the authorities.

This catalogue could easily be extended. But though one's suspicion may be aroused by the recital of such histories, the attention should be directed to more specific symptoms.

As elsewhere in medicine, the significant and diagnostically important symptoms in schizophrenia are not the most impressive ones. The order in which they are given here is that of their diagnostic importance.

I. Thought Disorder

Bleuler regarded the loosening and breakdown of normal processes of association as the fundamental disturbance in schizophrenia, and therefore invented that name. Thinking is not disturbed because it starts from wrong suppositions which lead it astray; this would be the description of a certain type of delusional ideas. In schizophrenic thought disorder the single contents may be correct in themselves, but they are put together in a muddled and scattered manner. "There is an abundance of what one might term 'the knight's move' in association" (Mapother). Therefore, the result of thinking if uttered or written down often sounds like a silly joke, although not meant as such.

To give a few examples. A patient wrote in a letter to the hall porter of a hospital from which the former was absent on week-end leave: "If I should return during my absence, keep me here until I come back." Fragment of an interview between patient and physician: (In what way do you feel ill?) "You know the story of Adam and Eve? How Eve was tempted with an apple?" (What about your illness?) "All the people in the ward eat apples." (That is not unusual!) "In the ward the door is open and the window closed." (Yes, I think that is so.) "Nobody will be able to get to the apple-tree. . . . We are all ruled by electricity, all except my dog," etc. A schizophrenic patient mentions Napoleon and goes on to say that he was banished to Ellis Island. "That's where they psycho-analyse people" (W. L. Woods).

If the disturbance is so striking it is easy to recognize. In the beginning of the illness it may be very slight and only demonstrable under certain circumstances—for example, if one asks the patient to repeat a story or to explain a proverb or the point in a fable. The disorder may even only be a subjective symptom to which the patients react with uncharacteristic complaints. They speak of inability to concentrate, or complain that their ideas are diffuse or narrowed. But often the disorder is not regarded as an incapacity by the patient; on the contrary, he brings forward his vague nonsense as something quite natural, and feels himself not understood by the

persons of his environment. Simple things are expressed in a queer stilted language, and are uttered in the tone of mystical revelations. A student turns from science to what he calls philosophy. Uneducated people think themselves able to reform human life and solve the deepest problems.

It is sometimes not easy to differentiate this behaviour from the transitional intellectual inconsistencies of the adolescent age. Thought disorder in confusional states (due to intoxications or other severe cerebral impairment) is often of very similar incoherent kind. But in confusional states there is always a dimming or clouding of consciousness, which is clear and unimpaired in schizophrenia. In cases in which the state of consciousness cannot be ascertained the history and the somatic findings mostly make clear the nature of the disorder.

II. Disturbances of Volition

Symptoms which can be classified under this heading are easily overlooked, and are often only disclosed by direct questioning of the patient. Then he will say that he does not feel master of his will, his thoughts, or his activities; he is influenced by other people who make him think or do things; his ideas, words, or movements are not his own, he feels hypnotized, drugged, etc. These disturbances of volition, if expressed straightforwardly, are pathognomonic of schizophrenia. But there is often only a slackening of will-power, which may not be realized by the patient himself. This can be one of the first signs: the patient becomes unable to make any decision in the various things of daily life, as well as in important questions like marriage or choice of a profession. Well-educated intelligent men become idlers or vagrants without any detectable cause. As in most other schizophrenic symptoms, the striking change in the patient's behaviour compared with his former habits is important here.

It is sometimes impossible to distinguish psychologically the loss of volition in commencing schizophrenia from weakening of spontaneity in a neurasthenic or in a patient with organic deterioration. Circumstances and concomitant symptoms usually make differentiation possible. Moreover, slackening of will is not often the only volitional disturbance in schizophrenics. It occurs together with spells of unexpected hyperactivity, of absurd impulses, and with specific schizophrenic anomalies known by the terms "negativism" (morbid contrariness without any motivation) and "ambivalence" (presence of opposite tendencies, between which no decision is made).

Signs of this kind, if present, also permit the distinction of volitional weakness in schizophrenia from retardation in depressive states. This differential diagnosis can be difficult, especially if the depressive affect is not very pronounced. The affective anomalies characteristic of schizophrenia will, however, be of help here.

III. Inadequacy and Incongruity of Affect

The normal emotions of affection and sympathy for the patient's nearest relations or friends cool off or take on a quality of shallowness during a commencing illness. More primitive emotional reactions—for example, of fear or rage—are preserved longer. Some patients notice and complain of this loss of all warmth of affection: a similar complaint is often made by depressives, who do, however, in the very moment of making the complaint, show a normal affective response. In many schizophrenics their cool and uncouth behaviour is only remarked by their relatives: the patients deny it, or find nothing strange in their tactless or flippant manners.

It is due to the loss of affective response of the early schizophrenic that the physician is often unable to establish a natural rapport with his patient, in spite of efforts to do so. This test, if cautiously applied, can serve as a valuable diagnostic aid—for example, in cases in which early schizophrenia is disguised in the form of a neurosis.

The difficulty is that many persons of a schizophrenic diathesis show an inadequate affective response all their lives. In such people the onset of the psychosis may be signalized by gross anomalies of emotional reaction—for example, fatuousness, an out-of-place hilarity, or (of great practical and medico-legal importance) an unfeeling cruelty. Murder and similar crimes are often attempted and committed by unrecognized schizophrenics. The percentage of schizophrenics in institutions for criminal lunatics is much higher than that in the average mental hospital.

Incongruous affect—that is, an emotional response inappropriate to the circumstances—is more commonly seen in later stages of the illness. It needs skilled psychological observation to detect it in an early schizophrenic: it is a sign of great diagnostic value.

IV. Autochthonous Delusions

This symptom ranks first in respect of diagnostic significance among the *positive* symptoms of schizophrenia. It is the fundamental event from which are developed all paranoid schizophrenic states, and is especially noteworthy as the primary experience underlying ideas of reference and other delusions. As it is often cloaked in a secondary elaboration and in features derived from the personality and the environment, a few examples of its pure form may facilitate its recognition.

A patient said: "I went into a café, and there were three white tables; I looked at them, and suddenly I knew that this signified the end of the world." Again, "The clock was at eight; I knew from this that I had to devote myself to religion from now on." "There were red and white suits in the shop-window; this meant that I am of a different descent."

What is characteristic of these occurrences is that out of a casual and commonplace perception a morbid conviction has arisen. This conviction may have a definite content or meaning, or it may be quite vague and indefinite, "something terrible," "something extremely important," etc. It produces, or is perhaps produced by, a peculiar delusional attitude: one might say that the patient is submerged in an atmosphere of misinterpretation. It is unimportant from the diagnostic point of view whether the patient keeps to these delusional ideas or abandons them later on. The building up of a delusional system and the addition of explanation and justification are much less characteristic of schizophrenia than the original autochthonous experience, which in typical cases takes place out of a blue sky. It may be possible by industrious research to discover a connexion between the content of the delusion and previous experience, but this is of little significance. What is important is the readiness to plunge into a mystic conviction, which is beyond all reasoning with. The physician's natural efforts to understand the patient may obstruct his recognition of the morbid character of the delusional experience.

V. Catatonic Symptoms

These anomalies of motor behaviour were regarded as diagnostically specific by Kraepelin when he first created the concept of what to-day we call schizophrenia. They

have lost part of their significance since their frequent occurrence in so-called organic psychoses, especially in states of clouded consciousness, has been observed. Many catatonic features have been seen in encephalitis lethargica and after focal lesions of a like localization. Excitement and stupor in affective psychoses are sometimes indistinguishable from those in schizophrenia. Stereotypies, fixed attitudes, and mannerisms are easily recognized, but they belong as a rule to later stages of the disease.

In early schizophrenia one often finds a rather characteristic pre-stuporose behaviour, a kind of motor constraint lasting for hours or present all the time. To the layman the patients seem drowsy, but they are really not so; they are only as it were restricted in movement and speech. There is often insomnia, and headache is complained of. Others report states of rigidity, which is forced upon them for a short period at night. These akinetic states, and also periods of aimless restlessness, may be split off from everything else in the patient's mind and deprived of any true motivation. Sometimes the patients do not find anything abnormal in their motor peculiarity. A patient awoke from a stupor which lasted over weeks: when questioned why he did not move or speak, he only answered that he felt too bored.

VI. Hallucinations

These can occur in all types of mental illness. These characteristic of schizophrenia are significant not so much as hallucinations as by virtue of their combination with the symptoms mentioned before—voices reproducing the patient's thought disorder, containing neologisms; bodily sensations closely related to feelings of passivity or to catatonic movements; synaesthesiae with bizarre delusional contents—behind which the hallucination proper remains indiscernible. All these phenomena are relatively rare in early stages of the disease.

It must be remembered, however, that hallucinations in a state of clear consciousness are very common in schizophrenia, but uncommon in other psychoses. Isolated auditory hallucinations are most frequently met with. Commencing schizophrenics often describe phenomena in which they are unable to make a clear distinction between vivid thinking and actual hearing.

The attitude of patients towards their hallucinations is characteristic. Although they can distinguish between the false perception and a real one, they have no insight. Further, though convinced of the reality of their experiences, they may not draw the obvious conclusions or react in an unexpected way. For instance, a man who thought he was perpetually being molested by means of the telephone and the wireless took his complaints not to the Post Office or to the B.B.C., but to a psychiatrist.

Occurrence of Symptoms

Although all the schizophrenic symptoms mentioned in this survey may be found in one patient at the same time or in the course of his illness, many cases show a preference for one or for a small group of these symptoms and never exhibit the others. Thus, some patients develop shallowness of affect and thought disorder, but never have delusions or hallucinations. Some "catatonics" become only stuporose, without any psychological content; they may have a few hallucinations and autochthonous delusions in the introductory stage. There are "paranoids" or "paraphrenics" without demonstrable thought disorder and without disturbances of volition. In other cases the volitional anomalies may entirely predominate in the clinical picture. There is not one among

the main symptoms which cannot be absent in a case of schizophrenia provided the others, or some of the others, are present.

In view of this multiform symptomatology, numerous efforts have been made to establish one of the symptoms as the fundamental disturbance of schizophrenia. Although in each of these theories a certain core of truth is contained, none of them covers the facts with a satisfactory completeness.

General Qualities

There are, however, a few general and structural qualities of the schizophrenic picture which are of diagnostic value. The relative *clearness of consciousness* has been mentioned before. It can be present in states of severe motor excitement, in full-blown hallucinosis, and in deep stupor. The hallucinating schizophrenic who seems completely absorbed in his delusional world, but at the same time notes every detail in his real environment, is the classic example of this psychological picture which has been named "double orientation." It is perhaps not by pure chance that states of disturbance of consciousness like continuous sleep, hypoglycaemic coma, or epileptic fits seem to have some therapeutic effect on schizophrenia.

The *tendency to "splitting"*—that is, a non-systematic psychic disconnection, from which the name of the illness was taken—is another structural character evident in most cases. Fragmentation may separate ideas from accompanying emotions, mimic expression from proper affect, and speaking from thinking, but also a complex of delusional ideas may be separated from the rest of the personality and emerge only on certain occasions.

It has been said that many schizophrenic symptoms have a quality of peculiar *psychological remoteness from normality*. They are so far from normal understanding that they cannot be described in ordinary language. One cannot imagine what is going on in the patient as one can, to some extent, in all other psychoses. Thus, the reaction of the non-schizophrenic to the schizophrenic can be used as a diagnostic test. At the same time—and this is diagnostically much more significant—the patient himself finds his absurdities not at all strange, but quite natural, rational, and understandable.

As a final general character the *detachment from reality* (Bleuler's "Autismus") has to be mentioned. It often appears as an active withdrawal of the patient from anything that may disturb his delusional world. In later stages of the illness, if favoured by supporting circumstances, it produces a grotesque mental isolation of the patients. In the beginning a detached superiority of the patient to everything that really matters to him may provide the keystone of the diagnosis.

B. Albrigo (*Rif. med.*, 1938, 54, 1297) records two personal cases of aberrant vaccinia. The first was that of a woman, aged 25, vaccinated in infancy only and the subject of eczema of the vulva, who developed extensive vaccinia of the external genitals, perineum, and anal region. Infection in this case was probably due to her having scratched the eczematous lesions after attending to her recently vaccinated child. Subsequent vaccination on the arm had a negative result. The second case was that of a man, aged 38, who had been vaccinated in infancy and again at 18 years of age and was the subject of peri-anal eczema. The vaccinal nature of the peri-anal lesions in his case was shown by the production of a typical vaccinal keratitis after inoculation of the cornea of a rabbit.

INCIDENCE OF PATHOGENIC STAPHYLOCOCCI IN THE NOSE

BY

A. M. McFARLAN, M.B., B.Ch.

Walter Dixon Memorial Scholar

(From the Department of Medicine, University of Cambridge)

It has been suggested that a factor in the chronicity of some cases of furunculosis and osteomyelitis is the transference of pathogenic staphylococci by the patient's fingers from the nose to the skin or wound. Dolman (1935) found that staphylococci were present in the nose of nine patients with nasal sinusitis and also in the apparently healthy nose of several patients with staphylococcal infections elsewhere. Valentine (1936) obtained cultures of *Staphylococcus aureus* from the healthy nose of fourteen of eighteen cases of chronic furunculosis. In six out of seven of these strains the toxin production (α -haemolysin and Panton-Valentine leucocidin) was comparable to that of the strain isolated from the lesion elsewhere. Apart from the possibility of reinfection of a superficial lesion it is conceivable that pathogenic staphylococci in the nose may sometimes gain access to the blood stream and give rise to an acute osteomyelitis or a perinephric abscess. Thus it is of interest to gain an idea of the incidence of pathogenic staphylococci in the nose of individuals who are free from staphylococcal infection.

Individuals Studied and Methods Employed

During February and March, 1938, nasal swabs were taken from 101 undergraduates aged 18 to 22, thirty-three children in hospital aged 7 months to 16 years, and thirty-one adults in hospital aged 19 to 75 years. None of these had or had recently had a staphylococcal or nasopharyngeal infection.

The nostrils were swabbed through the anterior nares with sterile cotton-wool swabs mounted on a probe. Since the work of Thomson and Hewlett (1895) it has been agreed that, in a healthy nose, cultures from the walls of the nasal cavities proper yield relatively few organisms, while the vestibule, the vibrissae, and crusts of dried secretion yield a plentiful and varied growth (Küster, 1929; Cruickshank and Cruickshank, 1931). From the point of view of a possible source of infection of the patient's fingers it is the vestibule which might be important, so that it is no disadvantage in this investigation that the majority of the organisms obtained on the swabs came from that source.

A swab from each nostril was smeared directly on half an agar plate. The plates were incubated at 37° C. for twenty-four hours. Films were made of suspicious colonies, and when staphylococci were found two or three representative colonies were subcultured into a broth tube. When both *aureus* and *albus* were present colonies of each were examined. The broth cultures were incubated at 37° C. in an atmosphere of 30 per cent. carbon dioxide for forty-eight hours. After centrifugation the supernatant fluid was tested for α -haemolysin by diluting 0.1 c.cm. with 0.4 c.cm. saline, adding 0.5 c.cm. of a 2 per cent. suspension of thrice-washed rabbit red cells and incubating at 37° C. for an hour. A control tube containing 1 unit of antitoxin was set up for each fluid. In a few cases where haemolysis occurred in the control tube, proof that the α -haemolysin was responsible was obtained by showing that the antitoxin neutralized

a greater dilution of the fluid. A loopful of the sedimented cocci was inoculated into a sterile stoppered tube containing 0.5 c.cm. of a 1 in 5 dilution of human oxalated plasma in saline. The presence or absence of coagulation was noted after three hours' incubation at 37° C. and confirmed after the tubes had stood on the bench overnight. One per cent. mannite peptone water tubes were also inoculated, and were read for acid production after twenty-four hours, and after seven days' incubation.

Strains of Staphylococci-

In all, 167 strains of staphylococci were studied, and the results are given in Table I.

TABLE I.—*Properties of Staphylococci Isolated from the Nose*

Strain	No	Haemolysin		Coagulase		Mannite	
		+	-	+	-	+	-
<i>Aureus</i>	59	55	4	51	8	55	4
<i>Albus</i>	108	23	85	23	85	29	79
Haemolysin + ..	78			74	4	74	4
—	89			0	89	10	79
Coagulase + ..	74					71	3
—	93					13	80

There is a high degree of association between *aureus* pigmentation, haemolysin production, coagulase production, and mannite production, which is in accord with the results of others. Four haemolytic strains produced no coagulation though tested on two samples of human plasma and on rabbit plasma on which other strains gave positive results. There is, therefore, not complete correlation of haemolysin production and coagulase activity as recorded by Cowan (1938), but agreement of the order found by Hallman (1937), Saski and Fegjin (1937), Cruickshank (1937), and Fisher (1936). Flaum (1938) records even more divergent results. The discrepancies are possibly due to differences in the plasma used or in the method of toxin production. It is, however, generally agreed that haemolysin-positive coagulase-positive strains are pathogenic. The four haemolysin-positive coagulase-negative strains in this series have been classed as pathogenic. They all occurred in the undergraduate group, and the figures are not greatly affected by their inclusion.

The figures in Table I and Cowan's results suggest that a very high proportion of *aureus* strains are pathogenic and a high but lower proportion of *albus* strains non-pathogenic. The percentage of *aureus* strains in a series can therefore be used, in default of other information, as a rough estimate of the percentage of pathogens.

Incidence of Staphylococci in the Nose of Healthy Persons

The numbers of persons in the various groups found to be carrying staphylococci in the nose are recorded in Table II, with the percentages and their standard errors. As mentioned above, swabs were taken from both the right and the left nostril. In most cases the growth from the two nostrils was similar. In fifteen cases the growth from one side was heavier or contained more *aureus* and less *albus* colonies than the other; but such differences were slight, and the results are given as positive or negative for each individual.

TABLE II.—*The Number of Persons with Staphylococci in the Nose*

Group	No.	Staphylococci Present		Haemolytic Staphylococci	
		No.	% ± S.E.	No.	% ± S.E.
Children in hospital (7 months to 16 years) ..	33	24	72.7 ± 9.1	19	57.5 ± 8.6
Adults in hospital (19 to 75 years)	31	27	87.1 ± 6.5	13	41.9 ± 8.9
Undergraduates (18 to 22 years)	101	91	90.9 ± 3.0	33	34.4 ± 4.7
Total	165	142	86.1 ± 2.9	67	40.6 ± 3.8

The results are similar to those obtained by Hallman (1937). The figures in Table III have been extracted from her paper and the standard-errors calculated.

TABLE III.—*The Number of Persons with Staphylococci in the Nose (Hallman, 1937)*

Group	No.	Staphylococci Present		Coagulase + Staphylococci	
		No.	% ± S.E.	No.	% ± S.E.
Children in hospital (2 months to 12 years) ..	272	201	73.9 ± 3.1	159	58.4 ± 3.0
Children in hospital (13 to 19 years)	38	30	70.9 ± 8.3	23	60.5 ± 7.9
Adults in hospital (over 19 years)	49	37	75.5 ± 7.1	22	44.9 ± 7.1
Students	109	87	79.8 ± 4.3	40	36.7 ± 4.7
Total	468	355	76.3 ± 2.3	244	52.1 ± 2.3

The different percentages of carriers of pathogenic staphylococci recorded in the totals are due to the large number of children in Hallman's series. The difference between the carrier rates in Hallman's students and younger children is 21.7 per cent., which is more than thrice its standard error 5.6, and there is a difference of 23.1 per cent. between the undergraduates and children in my series, which is more than twice its standard error 9.8. Thus the differences in carrier rates of these groups are more than are likely to have arisen from sampling errors. Too much stress cannot be laid on the striking similarity of the carrier rates in comparable groups of the two series, since there are differences in the percentage of persons carrying non-pathogenic staphylococci, and neither author found the coagulase and haemolysin tests completely parallel. In both series the carrier rate of non-pathogenic staphylococci is higher as the carrier rate of pathogenic strains is lower. It is safe to conclude that in two samples of healthy and active young adults one of every three was found to be carrying pathogenic staphylococci in the nose. In adults in hospital the carrier rate was higher, but the numbers involved are not sufficient to make the difference certain. In children in hospital three out of five were carriers.

The statement of a carrier rate does not give a measure of the chance that an individual will be a carrier if observed over a period of time. Dudley (1932), during a year's observation of diphtheria carriers in a school, found that, with an average carrier rate of 6.6 per cent., 40 per cent. of the boys were carriers at one time or another. Davis (1921) concluded that cultures taken at short intervals from the throat of normal persons soon or later revealed the presence of haemolytic streptococci in practically all of them. Hart (1937) noted during a 6 months' study of the nasal and pharyngeal flora of an operating theatre staff that there were many intermittent carriers of *Staph. aureus* and few persistent ones. The

figures he obtained for the carrier rate (Table IV) are of interest because they show a greater variation among the same community over a period of time than was shown between the various groups of the series recorded above.

TABLE IV.—Carrier Rates in an Operating Theatre Staff (Hart, 1937)

Group	Date	No.	Staphylococcus Aureus Present	
			No.	% \pm S.E.
Operating theatre staff ..	Jan. 20	57	35	61.4 \pm 6.5
	Jan. 29	44	44	100
	Feb. 7	53	14	26.4 \pm 6.1
	Sep. 30	56	9	16.1 \pm 4.9
General population ..	Jan. 23	54	39	70.4 \pm 6.2

Bloomfield (1921) found *Staph. aureus* present in the throat only as a transient parasite except when there was a definite local infection. Eight laboratory workers examined by him carried *Staph. albus* constantly in the nose over a period of three months, while *Staph. aureus* was only occasionally present. Personal observations on patients in hospital showed that haemolytic staphylococci were not always isolated from later swabs of the nose of a patient whose first swab had been positive a few weeks before.

These observations and analogies make it evident that there is considerable variation from one community to another and in the same community from time to time in the percentage of persons carrying pathogenic staphylococci in the nose, that in healthy and active undergraduates the carrier rate may be one in three, and that the great majority of healthy individuals are carriers from time to time.

Incidence of Staphylococci in the Nose of Patients with Staphylococcal Infections

Owing to the limitations of available clinical material the incidence of pathogenic staphylococci in the nose of patients with staphylococcal infections has been studied only on small numbers of individuals. The methods used have been the same as for healthy persons, and the figures are given in Table V.

TABLE V.—The Number of Patients with Staphylococci in the Nose

Author	Group	No.	Staphylococci Present		Haemolytic Staphylococci
			No.	% \pm S.E.	
McFarlan	Osteomyelitis (over 19 years)	10	10	7	70.0 \pm 14.5
	Boils and carbuncles (over 19 years)	19	18	13	68.4 \pm 10.7
	Total	29	28	20	68.9 \pm 8.6
Hallman	Osteomyelitis (19 years or under)	22	20	11	50.0 \pm 10.7
	Osteomyelitis (over 19 years)	29	22	13	44.8 \pm 9.2
	Total	51	42	24	47.1 \pm 7.1
					Coagulase + Staphylococci

The figures in my series suggest that there is a higher incidence than in persons with no staphylococcal infections, and the difference (27.0% \pm 12.4) is more than would often arise from errors of sampling. Yet Hallman's figures do not show a similar difference, and it would be premature to conclude that the incidence is in fact higher. In nine undergraduates who had had a series

of boils a year or more before investigation and were then free, there were seven who had haemolytic staphylococci in the nose. This shows that the local condition does not necessarily recur when pathogenic staphylococci are present in the nose. The growths of staphylococci obtained from the nose of some patients with staphylococcal infections were pure *aureus* and more profuse than usual, but similar growths were obtained occasionally from healthy persons.

It is certainly possible that pathogenic staphylococci may be transferred by the patient's fingers from the nose to a lesion elsewhere. The figures recorded here show that pathogenic staphylococci are so often present in an apparently healthy nose that it is reasonable to take all possible precautions to prevent reinfection from that source. Yet the frequency with which pathogenic staphylococci occur in the nose of healthy persons makes it possible that their presence in the nose of patients with staphylococcal infections in other parts of the body is merely a reflection of the carrier rate of the community in which they are living. If the serological types of staphylococci prove to be as stable and numerous as Griffith's streptococcal types it may be possible to obtain evidence in favour of the occurrence of reinfection from the nose by finding that the nasal strain is serologically identical with that isolated from the lesion elsewhere. At present the isolation of pathogenic staphylococci from the nose of a patient with a chronic staphylococcal infection cannot be considered as proof that reinfection is occurring.

Summary

1. Pathogenic staphylococci were isolated from the healthy nose of 34 per cent. of healthy undergraduates, 42 per cent. of adults in hospital, and 58 per cent. of children in hospital. Similar figures for the incidence in individuals with no staphylococcal infection have been obtained by Hallman in a larger series.

2. It is suggested that the great majority of healthy individuals are carriers from time to time.

3. Pathogenic staphylococci were isolated from the healthy nose of 69 per cent. of patients with staphylococcal infections elsewhere.

4. The isolation of pathogenic staphylococci from the healthy nose of a patient with a chronic staphylococcal infection is not in itself proof that reinfection from the nose is responsible for the chronicity of the infection, though the possibility of such reinfection cannot be denied.

I wish to thank Professor Ryle and Dr. E. T. C. Spooner for facilities and encouragement, Dr. A. Bradford Hill for advice on the statistical part of the paper, and Dr. R. A. O'Brien of the Wellcome Physiological Research Laboratories for a supply of staphylococcus antitoxin.

SULPHONAMIDE IN THE TREATMENT OF ACUTE MASTOIDITIS

BY

V. G. HORAN, M.B., B.Ch.

Surgeon Lieutenant-Commander, R.N.

AND

S. GAY FRENCH, M.B., B.S.

Surgeon Lieutenant, R.N.

We feel diffident in making claims for a preparation which, by reason of its initial success, may have had an inflated popularity, but the results given below seem to be striking enough to warrant publication. The inconclusiveness of first results is well known, and these figures are published in the hope that further investigation and use of the drug by others will lead to its acceptance as a most useful prophylactic during the course of the all-too-common otitis media. The method of administration which has been carried out at the Royal Naval Hospital, Chatham, during the past year has been as follows:

All cases of acute suppurative otitis media (A.S.O.M.) were placed on "colsulanyde" (Crookes's), 1 drachm four-hourly by mouth, as soon as they were admitted. In addition they received the treatment of the acute ear which has been accepted practice for generations—namely: myringotomy, if the tympanic membrane was showing evidence of retention of pus, whether perforated or not; syringing of the ear thrice daily with saline or a solution of boric acid, followed by drops, those mostly used being gutt. hydrarg. nit. dil., gutt. acid. boric. in spirit, gutt. glyc. acid. carbol., and where the tympanic membrane was inflamed, intact, but not bulging, "sedonan" or "otalgan"; constant inhalations of tinct. benzoin. co. and menthol, and attention to nasopharyngeal and sinus infection. They also had a smart sulphur-free purge on admission, and a sulphur-free analgesic, such as aspirin.

During the year following the introduction of this routine the ratio of acute mastoiditis to acute otitis media has been greatly reduced, in this series from 22.7 per cent. to 4.5 per cent. That the accuracy of these figures is open to question is beyond doubt, for many different factors come into play in assessing results of this kind. The possible causes of error will be discussed later. The figures were obtained from the statistical returns of the hospital, and the average for the years 1934, 1935, 1936, and the early half of 1937, when sulphonamide was not being used, is compared with the year comprising the latter half of 1937 and the early half of 1938, when the above routine was employed. The figures for "acute mastoiditis" are those cases which were actually operated upon, and which were therefore surgically proven.

	A.S.O.M.	Acute Mastoiditis
1934	245	41
1935	177	33
1936	152	58
1937 (first half)	33	6
Total	607	138

Percentage of cases of acute suppurative otitis media to develop acute mastoiditis, 22.7.

	A.S.O.M.	Acute Mastoiditis
1937 (second half)	69	2
1938 (first half)	86	5
Total	155	7

Percentage of cases of acute suppurative otitis media to develop acute mastoiditis (sulphonamide used), 4.5.

Furthermore, during the period January, 1934, to June, 1937, the number of deaths per annum from the complica-

tions of acute suppurative otitis media averaged 2.85, while during the period June, 1937, to June, 1938, there were no deaths from this cause.

No claims are made in regard to the efficacy or otherwise of the drug in the treatment of otitis media *per se* (this side of the question is still under investigation), but the figures are consistent with the view that it is a preventive of the complications of this disease. Secondly, it is not claimed that every case of otitis media was streptococcal in origin, for not all of them were swabbed. All those in which swabs were taken proved to be due to a haemolytic streptococcus, and during the past winter and spring there has been, in the district from which these cases came, almost a streptococcal epidemic, comprising tonsillitis, scarlet fever (which has been very severe), etc.

The incidence during the years 1934 to 1937 (first half) may seem to be unduly high. However, the Royal Naval Hospital at Chatham draws its patients largely from establishments where a great number of individuals are massed together, and especially from those training establishments in which a large number of boys of the ages of 16 and 17 are accommodated. In this environment it is possible that an infecting organism may rapidly reach a high state of virulence, passing as it does through a large number of individuals of the age (at the boys' training establishments) when mastoiditis is most common and, in the case of the newly joined, finding an easy and non-resistant prey, often equipped with predisposing conditions such as massive pads of adenoids. The same treatment was adopted for any case of scarlet fever which developed otitis media, and these have been shown among the "A.S.O.M." section. Only one of these patients developed acute mastoiditis.

From the above it will be seen that the sulphonamide was used in a purely "shotgun" manner, and it is contended that the results justify its use, for, even if the otitis does not respond to the treatment and mastoiditis develops, no harm has been done and the patient's resistance is in no way impaired by the drug. In no case was the administration of sulphonamide prolonged for more than fourteen days, as it was considered that by the end of this time any good which would accrue from this mode of treatment had already been done, and, conversely, if the drug had failed, then no good purpose was being served by its continuance.

Chronic otitis media has not been considered in the above group of patients, the vast majority of whom had no previous record of otitis media.

Points Noted during the Series

In a small minority of cases colsulanyde, 1 drachm four-hourly, caused in the course of a few days a noticeable cyanosis, though no subjective symptoms were complained of by the patients. In these cases the sulphonamide was stopped for a few days and then begun again on a dosage of 1 drachm thrice daily. None of them showed any evidence of a true sulphaemoglobinaemia when tested spectroscopically, and Long and Bliss (1937) mention that they were not convinced of the existence of this condition.

A leucocyte count was performed as a routine on admission, and the tendency appeared to be for this count to drop after a few days' treatment, especially in those cases which already had a raised white count on admission, and a slight relative lymphocytosis appeared to be the rule. There was, however, little change in the blood picture relevant to otitis media, and this subject (the changes in the blood picture during sulphonamide treatment) is under investigation by Surgeon Commander McIntyre, to whom we are indebted for his co-operation.

The patients were not placed on a sulphur-free diet, as has been recommended by some, though sulphur-containing drugs were avoided in the concomitant treatment.

Discussion of the Results

It will be at once apparent that the percentages given above for the fall in mastoid incidence are open to question as regards their absolute accuracy. The seasonal and yearly incidence of mastoiditis varies widely and is naturally worse in an epidemic year, but it is claimed that, so far as Chatham is concerned, the last twelve months have included an epidemic. This, then, may be taken, if not as an error on the right side, at least to cancel out, more especially as the streptococcus had been active in many parts of the country during the early spring of this year.

Another cause of error which weights the scales in favour of the drug is the tendency of the surgeon, striving to show results such as these, to adopt a more expectant line of treatment of mastoiditis than he has formerly been accustomed to carry out. While the existence of the "doubtful" mastoid is undeniably common, there are a large number of cases which anyone would be forced to diagnose as acute mastoiditis, and even the most expectant treatment would not be able to reduce the mastoid ratio to the extent given above without an increase in the fatalities. Nor was the drug found to produce a "false cure," as Anwyl-Davies (1937) alleges it to do in gonorrhoea, though this side of the question is still under investigation and to be proved conclusively will need figures taken over more than one year.

It is reasonable, too, to assume that sulphonamide would have a beneficial effect on the course of acute streptococcal mastoiditis, because this drug is known now to be specific for the organism. The figures already published, from the original ones of Colebrook and Kenny to the most recent, all show that the virulence of the organism to the human body is reduced; and since in the type of mastoiditis under review, the virulence seems to be a big determining factor in the infection or escape of the mastoid process, the results might almost have been forecast, though it is gratifying to see them work out in practice.

What, in our opinion, is of the utmost importance is the early administration of the drug at a time when there is no question of mastoid infection. Probably pus is present in the mastoid antrum in many cases of otitis media, but this is still confined within a layer of mucous membrane. It is asking too much of any non-surgical measure to effect a cure after this membrane has broken down and there is already osteitis of the mastoid process, though Montandon (1937) reports two cases in which sulphonamide was given as a premedication before mastoidectomy and the condition settled without the need for operation.

It seems plausible to imagine that the sulphonamide reduces the streptococcus in the middle ear to a virulence low enough to enable the antrum to shut itself off by granulations (which it undoubtedly does in middle-ear infections of a low virulence), and thus guards against the all-too-common type of case where very acute mastoiditis develops within a few days of the onset of the otitis media. None of the seven cases operated upon during the second half of 1937 and the first half of 1938 were of this type; they were all operated upon because of a persistence of the discharge, coupled with a low pyrexia, slight mastoid tenderness, and a high leucocyte count. Sulphonamide in these cases appeared to have failed; this is a well-known phenomenon, and one for which no explanation is offered.

In all cases the mastoid cells were found to be hopelessly involved.

In fact, since the adoption of this line of treatment the classical "acute mastoid" has become a rarity in the hospital.

Conclusions

In spite of the possible sources of error in the figures published above, the incidence of acute mastoiditis in the Royal Naval Hospital, Chatham, has been notably reduced. Since the only difference in the accepted treatment of the acute ear has been the introduction of routine administration of sulphonamide on admission, it is reasonable to suppose that the aforementioned drop in mastoiditis is due to the drug. Therefore the sulphonamide group of drugs have a very real place in the treatment of acute suppurative otitis media.

We would like to express our indebtedness to Surgeon Rear-Admiral Dudley for his invaluable assistance in compiling these results.

Clinical Memoranda

The Use of Prontosil in Sprue

As early as 1914 I recorded two cases of sprue, with prominent soreness of the mouth, in which lasting benefit followed the use of autogenous streptococcal vaccines prepared from cultures from the sore tongue. In 1918 I published seventeen further cases, and suggested that oral streptococcal infection might play a part in the aetiology of sprue, even if it is only a secondary infection. Later in that year Dr. Lucius Nicholls confirmed my observations regarding the beneficial effects of autogenous oral streptococcal vaccines in sprue, and pointed out that his cultures belonged to the non-haemolytic *Streptococcus viridans* type. In 1920 I reported on forty-four cases of sprue treated in Calcutta by the vaccines, in addition to milk diet and drugs for controlling the looseness of the bowels, and compared the results with those in forty-five cases that I had analysed from the earlier Calcutta European Hospital records (Rogers, 1921). In the old series, which were probably more severe on the whole than the vaccine series, there were no recoveries while in hospital, and only five cases had greatly improved. In the vaccine series twenty-one had recovered, eighteen of them remaining well for upwards of one year, and thirteen, mostly more recent cases, had greatly improved. In six other cases relapses occurred. Later I obtained good results with the vaccines in clearing up the symptoms of sore mouth, followed by much gain in weight with cessation of the diarrhoea, in patients treated at the Hospital for Tropical Diseases, London; but it is difficult to assess the relative influence of diet and vaccines respectively.

A recent experience leads me to return to the subject. During the last five years I have from time to time attended for sprue a retired Indian tea-planter living in the country and now over 80 years of age. Since he moved to Southwold I had not seen him, until recently Dr. E. C. Cordeaux reported to me that his condition had become serious, being complicated by a fall of haemoglobin to 48 per cent., and by febrile bronchitis. On August 2, 1938, I saw the

patient with Dr. Cordeaux, but found he was already improving, with decline of the fever and the bronchial symptoms, following prontosil rubrum orally and injections of liver extract. The stools before the treatment numbered up to seven daily, and the use of prontosil was immediately followed by a fall in temperature and a decline of the stools to two or three daily, a result which Dr. Cordeaux had no doubt was due to the new drug. I have since heard that the soreness of the mouth has also greatly declined, and this confirmed the impression I had formed that the prontosil may possibly have exerted a beneficial action on the oral streptococcal infection, the presence of which I had verified by cultures at an earlier date; I had not, however, been able to give more than two or three vaccine injections some two years ago.

Of course, no conclusions can be drawn from improvement, which may be only temporary, in a chronic case of sprue. It is only the improbability of opportunities arising for a reliable test of the prontosil group of drugs in this depressing and intractable disease that prompts me to suggest its cautious trial, in moderated doses and for a limited period.

Salyrgan in the Reduction of Localized Oedema of Traumatic Origin

The remarkable effect of salyrgan in the reduction of dropsy in medical cases led me to consider the advisability of its use in surgical oedema. [The official preparation, mersalyl, listed in the Addendum to the *British Pharmacopoeia*, is the sodium salt of salicyl-(γ -hydroxymercuri- β -methoxypropyl)amide-O-acetic acid.]

The first case was that of a man with a cut finger and hand which had healed well, but, as often happens, recovery was delayed by some oedema. One intramuscular injection of 1 c.cm. of salyrgan produced a diuresis of about 100 per cent.; there was a considerable and sudden improvement in the movement of the fingers and a great reduction of the swelling. A few days later the injection was repeated, with a further satisfactory result. This case showed that the diuresis produced was accompanied by a diminution of a given localized oedema. The discovery of an adjunct to physiotherapeutic treatment seemed to have been achieved, and, accordingly, the procedure was put to further tests.

OTHER CASES TREATED

Severe Fracture of the Lower End of the Radius.—Ten days after the injury two injections of salyrgan produced a considerable difference in the oedema, and within five days no oedema remained.

Fracture of the Tibia and Fibula.—This was a malunited fracture which was wired in good position. Six weeks later, on removal of the plaster, union had occurred, but there was considerable oedema, which was greatly reduced within twenty-four hours of the injection of salyrgan.

Ununited Fracture of the Tibia and Fibula.—Treated with inlay bone grafts. On removal of plaster six weeks later there was pronounced oedema, which was uninfluenced by an injection of salyrgan.

Sepsis Hand.—The little finger and fifth metacarpal had been removed for sepsis. Traumatic arthritis of the left wrist

and considerable peri-articular oedema benefited immediately as a result of salyrgan injections.

Fracture of the Os Calcis.—Treated by Bühler technique. The patient evinced considerable pain on walking about in plaster. Salyrgan was given, and the next day the patient was free from pain and the foot felt lighter and looser within the plaster. In this case the relief lasted but a few days, and repeated injections were necessary before a satisfactory result was obtained.

Fracture of Lower Limb.—Several cases of lower limb post-fracture oedema, first noted when the patients began to walk, benefited extensively and immediately. A few cases, however, failed to respond.

Oedema of a Thigh Stump.—Amputation for suppurating tuberculosis of knee-joint. The oedema diminished so that the Unna-paste covering, placed to prevent post-operative swelling of the stump, became quite loose.

CONCLUSIONS

1. Salyrgan given intramuscularly is useful in reducing localized oedema after injuries.
2. For some unknown reason a number of cases fail to respond.

Senior Surgeon, British Hospital.

Severe Night Blindness due to Vitamin A Deficiency

The following case illustrates the rapid response to treatment that can occur when gross lesions due to vitamin A deficiency are present. It shows a striking difference from the extremely slow progress of the average beriberi case under treatment.

CASE RECORD

A Malay youth aged 18 was admitted to the Brunei Government Hospital on June 3, 1938, complaining of inability to see clearly at night. His vision was so poor at night that he could not find his way about without help.

On admission he looked a poor specimen: his weight was 86 lb., his skin was dry, and numerous black keratinous plugs blocked the sweat pores of the face. The conjunctivae were dry and lustreless, but no ulceration was present. His diet consisted of polished rice, fish, and bread, with small amounts of vegetables twice weekly. He showed no signs of beriberi. No elaborate apparatus was available for testing his capacity for dark adaptation, but the deficiency was so severe as to be easily demonstrable. He was taken into a darkened room, in which a normal person's vision was 6/9 with the ordinary test types, and at a distance of one yard from the test type he could with difficulty read the line D 60 (visual acuity 1/60). In daylight his vision was 6/5. He was given 36,000 units of vitamin A by the mouth (four capsules of haliverol, Parke, Davis and Co.), and was again tested in the darkened room one hour later. His visual acuity was now 6/60, and at one yard distance he could read the line D 12.

He was put on a liberal mixed diet in which local unpolished rice was substituted for the polished variety. Four capsules of haliverol were given three times daily, and cod-liver oil drops were instilled into the eyes twice daily. At the end of a week there was a great improvement. In the darkened room his visual acuity was now 6/9, but his skin was still dry, although the conjunctival sacs were moist.

On June 18, a fortnight after admission, his visual acuity in the darkened room was 6/6 partially; his general condition was also much improved, his skin was smooth and moist, and there were few horny plugs showing on the face. He had gained 8 lb. in weight.

He was discharged on June 30 fit and well.

Medical Officer.

Reviews

RADIOLOGY OF THE DUODENUM

Le Duodénum: Atlas de Radiologie Clinique. By P. Cottenot, Max Lévy, and Ed. Chérigé. Preface by M. Robineau. (Pp. 223; 496 figures. 285 fr.) Paris: G. Doin et Cie. 1938.

Since the war there has been not only great advance in x-ray technique but also a wider dispersal of x-ray apparatus, so that there are many more workers in the country. For their instruction and refreshment of knowledge a series of reference books have appeared, especially in the United States and in France. There is so much variation in the normal and abnormal appearances of even such a small portion of the body as the duodenum that a large textbook is needed to cover the subject adequately. Such a one has recently been produced by three workers in Paris and published by the well-known firm, Doin et Cie. The authors have brought together all variations of the normal and pathological radiographs of the duodenum, with a minimum of explicatory text, allowing the radiographs to be elucidated by semi-diagrammatic drawings, and have been well served by the publishers. In a short chapter on the technique for radioscopy of the duodenum they mention the essentials; they advocate the Berg compression bag to obtain strial pictures, and point out the need to see every portion of the duodenum in profile.

There is much variation in the appearance of the normal duodenum both in position and shape. Radiologists, or those to whom x-ray prints are submitted, must be prepared to allow for this and for anomalies caused by insufficiency of the mesentery or by fixation or variations in length bringing about redundancy. The position, filling, and movement of neighbouring organs must be taken into account in diagnosis. There is very full treatment of the appearances of duodenal ulcer and many illustrations of its varieties and the differential diagnosis. Duodenal diverticula are discussed and the fallacies that may make their interpretation difficult. As well as partly filled portions of small intestine which may be superimposed, there are dilated orifices of the ducts from pancreas and gall-bladder. As well as the ampulla of Vater, the duct of Santorini may be noted as giving rise to the appearance of diverticulum. Short but instructive sections deal with tumours of the duodenum, foreign bodies, or worms in this part of the alimentary tract, and the appearances of perforation of duodenal ulcer.

The last quarter of the book covers a discussion of the duodenum which has been subjected to operation, the effects of a normal gastro-entero-anastomosis, and stomal and jejunal ulcerations. The authors have brought a large amount of material together, and their atlas will find many grateful readers.

DEAFNESS AND HEARING AIDS

The Handicap of Deafness. By Irene R. Ewing, M.Sc., and Alex. W. G. Ewing, M.A., Ph.D. (Pp. 327; 3 plates, including a frontispiece; 84 diagrams. 12s. 6d. net.) London: Longmans, Green and Co. 1938.

- The moral which is strongly urged throughout this book is that the problems consequent on deafness should be early and boldly faced by the doctor, the patient, and his relatives, in order that the ensuing physical and psychological handicaps may be minimized. The subject has

been treated with a view to a wide public, who would naturally approach the matter from divergent points of view. It forms a volume (albeit rather a large one) which a doctor might recommend to deafened adults who tended to become aggrieved because of their disability and loath to take any active steps to overcome it by the use of a hearing aid or by lessons and practice in lip-reading. The second part of the book might be read with profit by any intelligent parents, faced with the knowledge that their child was severely deaf, who were anxious to learn about modern educational methods of dealing with these unfortunate children, and to hear of successes which have been achieved by boys and girls with perhaps even greater defects of hearing than that suffered by their own child.

Besides its missionary purpose the book is important because it summarizes the results and opinion of the authors, who, with Dr. T. S. Littler, were pioneers in this country in the utilization of hearing aids for the educational use of severely deaf children. Also, at the request of many doctors, they conducted the first clinic for giving advice to deafened adults as to whether their hearing residue was such that they would be likely to benefit from an electrical hearing aid. They report that of 1,037 deaf people about whom this question was asked the reply was in the affirmative for 80 per cent. This is a very encouraging figure for the deaf. But it is acknowledged in the text that not every deaf person could buy, or would use, the hearing aid recommended by them. It is interesting to note in this connexion that the authors insist on recommending the instrument which they have found by scientific test to give the best reproduction of speech. This is of course idealistic, but the practical fact remains that some deaf people will only use smaller instruments, even if they can hear more clearly with better but larger ones. The individual notes of the deaf patients who have been given as examples would have been more interesting for medical readers if greater details of the history and results of medical examination had been included. This probably could not have been easily done by the authors, as cases were usually referred to their clinic after the medical profession had indicated that they could do no more for the patient. Now that hearing aid clinics have been started at several hospitals greater facility in obtaining details of the ear condition may be expected to make progress in the improvement of hearing aids more rapid; and, moreover, the deaf will have another advantage in that they will have an easy opportunity to obtain advice about hearing aids at an earlier stage.

PREVENTION THROUGH AETIOLOGY

Causes and Prevention of Disease. By William Harvey Perkins, M.D. (Pp. 713. 35s. net.) London: Henry Kimpton. 1938.

The charge is sometimes brought against the art of medicine that, while it proclaims from time to time some notable advance in medical knowledge, it is too little concerned to follow up such discoveries by putting them into operation in a practical way. This lag of achievement behind opportunity is perhaps more in evidence in the preventive field than in the therapeutic. A new remedial instrument, whether a method or a substance, can be conveyed to the bedside, tested there by the clinician, and, if found to work, straightway added to the armamentarium of the doctor. In the case of a proposed new preventive method the course of events is not so speedy. Organization is required to test the novelty on a sufficiently ample scale to carry conviction, and even then its final acceptance into the class of genuine effectives may have to be delayed until its results can be subjected to statistical

inquiry. In the book under review Professor W. H. Perkins of the Tulane University of Louisiana deals candidly with these alleged or surmised shortcomings of the preventive art. He admits that many lacunae exist in our knowledge of prophylaxis, but at the same time he deplores that so little of what is well known already to the medical preventive expert is being competently used by administrators for the control of community disease.

Beginning with causation and prevention in their relation to heritable diseases, the author proceeds next to explore the nutritional aspects of the problem. He then deals with poisons, ingested or parenteral, and discusses such physical agents as atmospheric pressure, radiant energy, and the lightning stroke. He regards pathogenic parasitism as a more or less fortuitous stage in a blind reaching out after amicable symbiosis. His excursions into this wide and diversified field are interesting and suggestive. In later chapters he rises from the material plane into the world of thought and emotion. He considers aetiology in its bearing on personality, behaviour, and mental states, and puts forward as essential for the prophylaxis of psychological and social disease conditions the training of people in the control of feeling and emotion and the use of their intellectual faculties, as well as in the appreciation of personal values and the acceptance of social ties.

With regard to eugenics the view is expressed that the physician in a community must be a potent force to create sane attitudes towards the improvement of the inheritance pattern. If he believes, he should speak out. By so doing he will add to his usefulness. In another place the author indicts the American public for its unintelligent acquiescence in the pressure of commercial firms trading in health drinks and attractively attired sweets. He draws attention also to the needless frequency of accidents of all kinds. In order to evade the perils of the modern world the individual should possess a sound well-balanced body, alertness of mind and understanding, co-ordinated voluntary control, and responsive reflexes. Rickety ladders, worn brakes of motor cars, unsafe scaffolding, and polished floors are preventable causes of injury. Unpredictable hazards are explosions, the collapse of buildings, and assault by man or animals, but even in these unforeseen emergencies the quick response will often save beyond expectation. "Nowhere near the limit has yet been reached in the prevention of preventable accidents."

A special merit of the book is the serviceable tabulation of the community diseases according to their origins, paths of transmission, portals of entrance to the human body, methods of specific therapy, and principles of control. In the spacious domain of his choice the author has left little unsaid. As an aid to speculation upon the ultimate origins of disease and the repression of its noxious influences his book will be found of value.

FACTORS THAT PROLONG GESTATION

Studies in Prolonged Pregnancy in Rats. By Finn Boe. *Acta Pathologica et Microbiologica Scandinavica*, Supplementum 36. (Pp. 146, 26 figures, 27 tables. Free to subscribers.) Copenhagen: Levin and Munksgaard. 1938.

Various methods have been used in the investigation of the hormone factors which are concerned in the maintenance of pregnancy and in the initiation of parturition. Dr. Finn Boe, in his "studies on prolonged pregnancy in rats," has described his investigations into the effects of procedures which cause a prolongation of the gestation. Like several previous observers he has found that the expulsion of the uterine contents can be prevented at full term by the administration of gonadotropic hormone

or of the ovarian hormones, and that a similar effect is also brought about in the rat when the pituitary is removed in the later stages of pregnancy. The effect on the foetal development varied with the hormone administered; when gonadotropic hormone from mare serum or oestrone was injected a pronounced inhibition of foetal development occurred; on the other hand, the weights of the foetuses were distinctly increased during the prolonged pregnancy when gonadotropic hormone from human pregnancy urine or progesterone was administered. From these results the author concludes that the effects of various types of gonadotropic hormone on pregnancy are essentially due to the ovarian hormones secondarily produced in the organism.

Unfortunately, in his interesting discussion of the action of the gonadotropic and ovarian hormones in pregnancy, the author has not taken into consideration the recent findings that oestrogens may play an important part in the control of the luteal function, and it is possible that some of the results which Dr. Finn Boe has attributed to the action of oestrin on the uterine contents may in actual fact be due to effects on the luteal activity.

Though the author, in his own words, has obtained "very little which can be said to throw light on the initiation of parturition," he has carefully collected many interesting results which may ultimately help in the elucidation of this very difficult problem.

PULMONARY TUBERCULOSIS IN THE APPARENTLY HEALTHY

La Tuberculose Pulmonaire chez les Sujets apparemment Sains et la Vaccination Anti-tuberculeuse. By L. Sayé. (Pp. 255; 88 figures, including 32 plates. 24 tables. 60 fr.) Paris: Masson et Cie. 1938.

An extensive literature has in recent years accumulated on the subject of pulmonary tuberculosis in apparently healthy groups of the population—students, nurses, army recruits, industrial employees, etc. In his book Professor Sayé reviews most of the papers that have been published from several countries in Europe and America, and adds his own valuable observations made at the University of Barcelona. Moreover, he discusses in detail the types of lesions that may be found during such mass examinations, and attempts to define their pathogenesis, trace their course, and suggest their management. It is obvious, however, as he frankly states in his introduction, that many problems arising out of this aspect of pulmonary tuberculosis still remain to be solved. The volume is illustrated by radiographs, many of which are reproduced full-size in part. Since the lesions depicted are often small and inconspicuous, reproductions of radiographs of such lesions need to be particularly good to be convincing. This has not been achieved by the publishers in every instance.

Professor Sayé traces the development of the systematic radiological examination of groups of the population. As far back as 1902, Salles published the results of the examination of 286 soldiers belonging to a battalion at the battle of Vincennes. Since 1909 Ledoux-Lebard had the chest of every patient examined by x rays before an operation. But it is only since 1920, when Myers in the United States began the examination of students, that much interest has been taken in such investigations. In 1921 Redeker initiated it for contacts in Germany; in 1923 Rist in Paris was charged with the routine radiological examination of all those seeking employment at the *Assistance Publique*, and Adler in Switzerland put it among army recruits. Since then the number of investigations and the variety of groups investigated has

increased yearly. Professor Sayé has therefore done a service in making available most of this work in a concise and readable form.

The last section of the book comprises a full discussion of B.C.G. vaccination. He admits the statistical errors previously made in assessing its value, adds some recent investigations on hypersensitivity following vaccination, and discusses the possible use of the method in adolescents. The account is particularly interesting for the inclusion of a description of the tuberculous lesions found in children who had been vaccinated about ten years previously.

Notes on Books

Like everything else about the "man of destiny," his diseases and their explanations never cease to excite interest, and *Napoleon: A Medical Approach*, by BORIS SOKOLOFF (Selwyn and Blount, 10s. 6d.), which is not strictly confined to medical aspects, contains plenty of attractive information about the great Napoleon. The author, who is stated to be working in a cancer institution, considers in detail the evidence about the incidence of malignant disease in the Napoleonic family. As the age of 40 approached a profound change took place in the Emperor's physical constitution; in 1913 the late Leonard Guthrie explained this as due to hypopituitarism, and Dr. Sokoloff now comes to the same conclusion.

The Human Body, by Dr. LOGAN CLENDENNING, which has now reached its third edition (Heinemann, 12s. 6d.), was written with the intention of explaining some of the intricacies of the human body to the intelligent layman. The success of the book indicates that the author has succeeded very well in his difficult task. He has taken great pains to bring his information up to date in his latest edition, and the book can indeed be recommended to medical practitioners who wish to read a general survey of modern knowledge of physiology. Dr. Clendenning has a critical mind and a wide experience of medical practice, and he discusses in an interesting manner problems of general medical concern, such as the influence of heredity and environment, the causation of high blood pressure, etc.

The safe, and at the same time efficient, radium treatment of lesions of the mouth, orbit, and antrum has long presented a problem of no small difficulty to the radiotherapist. In his monograph *The Construction of Vulcanite Applicators for applying Radium to Lesions of the Buccal Cavity, Lips, Orbit, and Antrum* (John Murray, 5s.) Mr. D. G. WALKER gives the results of three years' work carried out at the Middlesex Hospital in collaboration with the department of radiotherapy. About a third of the book consists of excellent photographs by Miss D. F. Clephan, illustrating constructional methods and modes of application. The apparatus described, in addition to combining efficient dosage with adequate protection, is specially planned to add to the comfort of the patient during irradiation. The book is a valuable record of great progress in an important field of radiotherapy.

The *Formulaire des Médicaments Nouveaux* was instituted in 1891 and has now attained its thirty-eighth edition (Paris: J.-B. Baillière et Fils, 70 fr.). The original editor was Bocquillon-Limousin and the present editor is Dr. R. WERTZ. The scope of the volume is somewhat similar to that of the *Extra Pharmacopoeia*. Drugs are described in alphabetical order and a short monograph is devoted to each drug. The chief information provided is the synonyms under which the drug is known, its chemical structure and properties, its therapeutic properties, and the manner in which it is used. A number of references to

recent work are included. The scope of the work is indicated by the fact that the index contains about a thousand titles. The volume will be found particularly useful by those who wish to obtain information regarding the nature of French proprietary drugs and preparations.

Allgemeine Pharmakologie, an outline for doctors and students by Dr. FRIEDRICH AXMACHER (Berlin: Julius Springer, RM. 9.60), is a short volume (189 pages) in which the author sets out certain general pharmacological principles. The subject is one of peculiar difficulty because pharmacology presents a vast mass of detail in which singularly few general rules are discernible, and such rules as exist are distinguished by the number and variety of the exceptions with which they are encumbered. The following are some of the problems dealt with: distribution and excretion of drugs, relation between concentration or dose and action and time; drug tolerance and allergy; alteration of drugs in body; synergism and antagonism of drugs; chemical constitution and pharmacological action. Dr. Axmacher has made important researches on fundamental problems in pharmacology and has a wide knowledge of the literature. Here he makes a judicious selection of his evidence and provides an excellent introduction to a difficult subject.

Preparations and Appliances

A DEVELOPMENT IN VITAMIN THERAPY

Hesperidin (vitamin P) tablets G.L. (Glaxo Laboratories, Ltd.) represent an interesting new development in vitamin therapy. Szent-Györgyi and his school concluded that certain of the manifestations of experimental scurvy in guinea-pigs were not amenable to treatment with pure ascorbic acid, but were cured with crude preparations of vitamin C. They also made clinical observations on cases of vascular purpura, and finally hesperidin, a flavone present in citrus fruits, was identified as an active principle with curative action in spontaneous capillary haemorrhages. Scarborough and Stewart, working in Edinburgh, have confirmed the activity of hesperidin in clinical cases. The compound is now made available for general clinical use. The dose suggested is about 1 gramme daily by mouth.

HIGH POTENCY CALCIFEROL

High potency "Ostelin" tablets (Glaxo Laboratories, Ltd.) each contain 50,000 units of vitamin D. The pharmacopoeial therapeutic dose of this vitamin for an infant is 5,000 units daily. The high potency tablets are intended for intensive therapy in cases of gross vitamin D deficiency and in certain other conditions. Satisfactory results have been described with this method in various disorders, including parathyroid tetany, rickets, chronic arthritis, and psoriasis. Overdosage of calciferol is known to produce characteristic toxic effects, and the high potency of the remedy indicates the necessity for care in its employment. The preparation is marked "To be taken only under medical supervision."

NICOTINIC ACID TABLETS

Nicotinic acid G.L. (Glaxo Laboratories, Ltd.) is put up in tablets, each containing 50 mg. nicotinic acid. In recent years it has been shown that this substance produces a remarkable curative action in pellagra and is effective by either oral or parenteral administration. The dosage suggested is 200 to 500 mg. daily.

NASAL JELLY

Nasal jelly (Glaxo Laboratories, Ltd.) contains the anti-virus of *B. pneumoniae* (of Friedländer), *M. catarrhalis*, and mixed streptococci. It is recommended for local application in the common cold, chronic rhinitis, and influenzal sinusitis.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 5 1938

THE WATCH ON THE THAMES

There are features of unusual interest in the report for 1937 of the medical officer of health for the Port of London, Dr. C. F. White, who, after ten years' tenure of this important position, has recently been appointed medical officer of health for the City. The report summarizes the revised instructions of the Board of Trade with regard to crew accommodation. These overdue reforms will be carried into effect in all new ships, and it is hoped that these fresh regulations may also stimulate owners to undertake reasonable and practical improvements in existing ships when opportunity occurs.

As an example of the deplorable conditions still ruling to-day, the case is cited of one ship in which no fewer than twenty-eight defects were reported by an inspector of the Port. It is satisfactory to record that the owners concerned had the necessary work put in hand immediately, while on its completion two members of the crew wrote grateful and appreciative letters to the Port M.O.H. on behalf of their shipmates. The report especially stresses the unhygienic conditions in small coasting vessels. "In the small ship there are no messrooms, no wash-place, no clothes lockers, no drying-rooms, no oilskin lockers." Food is kept in all sorts of places—in boxes in alley-ways and under bunks, and has even been found in water-closet compartments. Of 128 vessels, the subject of a special inquiry, thirty had no cooks. Tired men preparing their own food rely on the frying-pan, the tin-opener, and strong tea. It is thus scarcely surprising that digestive troubles appear to be very common among the crews of coasters. The hard lot of these men is further aggravated by the long hours of work, stated in some cases to total as much as 120 hours and reaching on an average 110 hours a week.

The report contains a most interesting account of the measures employed with regard to a ship in which rodent plague was suspected. The vessel arrived at Gravesend on July 1 with a general cargo from Far Eastern ports and showed a clean bill of health. Proceeding to King George V Dock, she was inspected on the following morning by a sanitary inspector and rat officer, when a "deratiza-

tion" certificate was produced, issued on April 28 in Kobe, where thirteen dead rats had been recovered after fumigation. The vessel continued to discharge cargo over the week-end, but on the morning of July 5 the sanitary officer was notified that a number of dead rats had been discovered in the holds, and that stevedores were complaining of the smell of the decomposing bodies. Further inquiries elicited the information that 261 rats had been caught and destroyed in the course of the voyage. Two dead rats, together with another freshly killed by the rat officer, were immediately dispatched to the Seamen's Hospital, Greenwich, where, in the case of two animals, macroscopic examination revealed a condition strongly suggestive of plague, while in films from glands and spleens bacilli morphologically identical with *B. pestis* were demonstrated. All work on the ship was stopped forthwith, and fumigation with hydrogen cyanide began the same evening. As a result 432 dead rats were taken from the ship, all of which were dispatched for examination. When, however, the holds were empty, a further space offering extensive rat harbourage was discovered, and a second fumigation was ordered, yielding another 103 dead rats. The difficulties of the Port health authorities were increased by several complicating factors. Before the discovery of the suspected rats most of the London cargo had already been unloaded, the greater part, fortunately, into lighters. Forty-three lighters were fumigated with the cargo *in situ*, and the remaining seven, which had discharged their freight, were also dealt with. In addition to the London cargo the ship carried goods consigned to Hamburg, including 20,000 cases of chilled eggs. This Hamburg cargo had to be unloaded before fumigation and reloaded, maintenance of refrigeration of the eggs further complicating the procedure. The report states that owing to the advanced degree of decomposition of the two rats which appeared to be infected, it was not found possible to confirm the diagnosis of plague by culture and animal inoculation.

This interesting account throws light on the magnitude of the task confronting the Port health authorities in such cases. To trace numerous lighters dispersed throughout the Port, to arrange for the follow-up of all personnel involved, and to ensure the collaboration of shipowners (for whom the necessary measures inevitably involve no small financial loss) demands a highly efficient organization, more especially since the time factor is so important. It is obvious how readily such a disease as plague might establish itself in the metropolis but for the constant vigilance of the Port of London health authority.

MALE HORMONES

The testicle of vertebrates has at least two functions: the first is the formation of germ cells; the second is the secretion of substances which are liberated directly into the blood stream—the male hormones. The failure of development of secondary sexual characteristics which follows castration of the young male has been recognized for centuries, but it was not until 1849 that Berthold demonstrated that this result of castration could be overcome in the cock by grafting testicles elsewhere. Much work has since been done on isolating the substance responsible for this effect. A crystalline substance with male hormone activity, androsterone, was isolated from urine in 1931 by Butenandt.¹ A closely related substance, testosterone, was isolated from bull's testicle in 1935 by David,² and other substances having androgenic activity have also been discovered. They are all steroids and are closely related to a group of compounds with oestrogenic activity and to another group with progestin activity.

Injection of pure male hormone into normal and castrated animals soon led to an understanding of its function. Zuckerman and Parkes³ in 1938 showed that the fur of the male hamadryas baboon changed after castration to that of the female, but prolonged treatment with testosterone propionate led to the gradual change from the greenish brown of the female to the grey of the male. The characteristic cape of the male was also restored. Injection of the same substance into a castrated immature rhesus monkey⁴ made the animal fiercer and more dominant. Flushing of the "sexual skin," such as occurs in the normal male, also came on gradually and the external genitalia grew appreciably larger. There was a notable effect upon the internal reproductive organs, which normally atrophy after castration. At necropsy the prostate, vas deferens, and Cowper's glands of the experimental animal were found to be as large as those of a normal mature rhesus monkey and histologically similar. In the female androgenic substances inhibit follicular maturation and luteinization and suppress the menses, as Zuckerman⁵ has demonstrated in the rhesus monkey. The observations of Papanicolaou and Falk⁶ suggest that androgenic hormone may cause a general muscular hypertrophy. Castration of a male guinea-pig led to a diminution in size of muscles which was most readily recognized in the temporals. These returned to normal after injection of testosterone

propionate but were unaffected by oestrogens. They found, too, that injection of gonadotropic hormone over a period of weeks gave rise to muscular hypertrophy in the normal guinea-pig but not in the castrated animal. They regarded this as additional evidence that the effect was wrought through the testicle. The injection of androgenic substances into the normal rat leads to a histological change in the pituitary gland, which according to Wolfe and Hamilton⁷ consists of a degranulation of basophil cells. They observed an even more striking effect in the castrated rat, in which the pituitary gland underwent remarkable changes, most notable of which was an increase in number and size of basophil cells with the formation of basophil signet ring or "castration cells." The pituitary gland of the castrated rat returns to normal after injection of male hormone.

In the human being male hormone is excreted in the urine in measurable quantities in both the male and the female. After a certain degree of purification the excreted hormone is estimated by measuring the comb growth in the caponized cockerel that follows injections of this material. Recently N. H. Callow, R. K. Callow, and Emmens⁸ have described an improved colorimetric method of estimating the amount of male hormone in the urine which has considerable advantages over methods of biological assay. The amount of male hormone excreted by the adult female is almost as large as that excreted by the adult male. In some disorders it may be much increased, as, for example, in cases of suprarenal cortical tumours associated with the clinical conditions of virilism or basophilism. R. K. Callow⁹ described a girl aged 6 in whom the excretion was of the order of twenty to forty times the normal: trans-dehydroandrosterone was isolated from the urine of this patient. It is evident that androgenic substances may be produced by some other organ as well as by the testicle, and it seems likely that the suprarenal cortical tumour was responsible for this in Callow's case.

A pure substance having male-hormone activity—testosterone propionate—is now being used in many different clinical conditions. Benign enlargement of the prostate has been treated by injections of male hormone in the belief that it is due to excessive secretion of oestrogenic substances thought to occur when the secretion of male hormone falls off in old age. A number of workers have reported benefit in selected cases in which the residual urine is small, but Clarke¹⁰ points out

that in his series of ninety-three mild cases of prostatic enlargement there was sustained improvement in a large number after no other treatment than instrumentation. There is obvious need for further carefully controlled work before the value of hormonal treatment of enlarged prostate can be assessed. There has been much talk about rejuvenating the aged by implanting monkeys' testicles into them. Venzmer¹¹ carried this treatment a step further by injecting male hormone into aged and prematurely aged subjects. He claimed good results, but made no attempt to control his experiments; and, after all, there is no evidence that the eunuch dies young—on the contrary, in many respects he never grows up. Desmaret and Capitain¹² have claimed beneficial effects from treating with male hormone a small series of cases of painful enlargement of, and cysts in, the female breast. Patients with irregular, painful, or retarded menstruation and with menopausal disturbances are also stated by these authors to respond well to treatment with male hormone. Similar results have been recorded by Loeser¹³ and by Foss.¹⁴ The effect of androgenic substances on a physiological castrate has been studied by Hamilton,¹⁵ who reported the case of a sexually underdeveloped male aged 27 in whom testosterone acetate and propionate caused definite growth of the genital organs associated with priapism. Similar results were reported by Foss¹⁶ in one case and by Kenyon, Sandiford, Bryan, Knowlton, and Koch¹⁷ in a group of seven cases. Carolli and Girrard¹⁸ recorded a male aged 54 with testicular atrophy, absent beard, and deficient axillary and pubic hair associated with a myxoedema-like infiltration of the skin. They described the condition as the "syndrome thyroïdo-testiculaire," and found the polypeptide nitrogen to be increased to 0.186 gramme per 100 c.cm. of blood. This fell to 0.036 gramme per 100 c.cm. of blood after treatment with testosterone propionate, rising again to 0.069 gramme after cessation of treatment and falling again to 0.026 when it was once more resumed. This was associated with disappearance of the myxoedema-like infiltration, and with increased suppleness of the skin. There was a return of erections, which the patient had not had for a year. Experimental evidence shows that injection of male hormone in normal and castrated animals has a masculinizing effect. Clinical evidence from the increased excretion of male hormone in sufferers from suprarenal corti-

cal tumour with basophilism, or of virilism in females, also suggests a masculinizing role for this hormone. The most obvious clinical applications of male hormone would appear to be, therefore, in men whose virility is incomplete or has regressed, and possibly in women whose uterus or breasts are over-active.

MATERNAL MORTALITY RATES

Maternal mortality has in recent years come in for so much public discussion that one notes with surprise that a striking fall in the maternal mortality rate in 1936-7 has enjoyed but little public notice. Indeed, the leader in the *Times* of November 1 dealing with the report of the Chief Medical Officer of the Ministry of Health for 1937 contains no reference whatsoever to this event. Despite the very considerable activities of local authorities in the provision of ante-natal clinics and hospital accommodation the maternal mortality rate showed, over a considerable period of years, no decline. Although, during 1928-31, the tendency was in a slightly downward direction, in 1932-4 the puerperal mortality rate per 1,000 total births was 4.04, 4.32, and 4.41 respectively—that is, substantially higher in 1933 and 1934 than in any of the years since registration of stillbirths. If the rates are compared on the basis of live births alone, it will be found that they remained fairly constant from 1911 to 1932. In short, the puerperal mortality rate was not falling in 1934. In 1935, 1936, and 1937 the puerperal mortality rates per 1,000 total births were 3.94, 3.65, and 3.13 respectively. Analysis of these figures shows that the greatest decline is in the puerperal sepsis mortality rate, the figures for the last four years being 1.95, 1.61, 1.34, and 0.94 respectively per 1,000 total births. There is little doubt that the discovery and use of sulphanilamide in the last two years have contributed to this reduction, although possibly a more important factor is the lower incidence of streptococcal diseases of all kinds. In this connexion it is significant that the figures for the notification of erysipelas for 1937 are lower than those for 1934 by 25 per cent. On the other hand, toxæmias of pregnancy show a rising mortality, though 86 per cent. of all investigated fatal cases (excluding cases of abortion and ectopic gestation) had received ante-natal care.

All other causes of death ascribed to child-bearing and pregnancy, including abortions, show a decline. It is reasonable to infer that there is in the country at present a higher standard of midwifery practice amongst general practitioners, midwives, and hospital staffs than was general ten years ago when the Departmental Committee on Maternal Mortality and Morbidity was making its investiga-

¹¹ *Diagn. med. Bull.*, 1937, 63, 1402.

¹² *Presse med.*, 1937, 46, 183.

¹³ *Lancet*, 1938, 1, 373.

¹⁴ *ibid.*, 1937, 1, 373.

¹⁵ *Endocrinology*, 1937, 21, 649.

tion. Whatever the value of the work undertaken at ante-natal clinics the conclusion must be drawn that some other factor or factors are responsible for this gratifying improvement in the figures for maternal mortality. Furthermore, it is desirable to place on record that the improvement has taken place before local authorities have had an opportunity of implementing the proposals contained in Circular 1705 of the Ministry of Health. Discussion on the subject of maternal mortality has too often evoked more emotion than accuracy, and it is as well that the profession and the public should realize this fact.

"WILKIE'S CHRONIC DUODENAL ILEUS"

The publication of the William Mitchell Banks Memorial Lecture for 1938 by the late Sir David Wilkie in the current issue of the *Liverpool Medico-Chirurgical Journal* is of special interest not only for its intrinsic value as a contribution to surgery but also because it records one of the last lectures delivered by Sir David before his untimely death. His writings, especially upon abdominal surgery, always commanded the greatest of attention and admiration among surgeons, but this dissertation upon chronic duodenal ileus deals with a subject which was peculiarly his own, and records an experience of the condition which is probably unparalleled. It was, indeed, an earlier article upon this subject in the *British Journal of Surgery* in 1921 which may be said to have aroused interest in the condition in this country. It has at times been referred to as "Wilkie's chronic duodenal ileus." Sporadic reports of acute duodenal ileus had appeared for many years previous to this; it was the special value of Wilkie's work that he recognized and described as a clinical entity the symptoms of a chronic form of the same lesion. In an early paragraph he addresses himself to the question: "Does a chronic obstruction of the duodenum occur as a pathological and clinical entity?" His conclusive answer is that there are abundant records by many observers of the demonstration of such obstruction both *in vivo* and at post-mortem examination. In these cases the obstruction resulted from many different causes, the chief being (a) congenital anomalies of intestinal rotation; (b) a drag upon the mesentery in visceroptosis and other postural defects; (c) infiltration of the mesentery by malignant disease; (d) pressure from enlarged mesenteric glands, tuberculous or lymphadenomatous; (e) cicatrization following anastomotic ulceration after gastro-enterostomy. The possibility that the condition may arise from an achalasia, as in Hirschsprung's disease of the colon, is also considered, although no cases of this type were met with. The chief complication of the condition is acute duodenal ileus and dilatation of the stomach, but stasis in the duodenum appears to predispose to the development of gastric and duodenal ulceration, since such ulcers were found in no fewer than thirty-five of the 135 cases operated upon. On the contrary, in only six cases was a recognizable cholecystitis present. The clinical picture, while in some cases unmistakable, is often "overcast and un-

convincing." Gastric flatulence is the most constant symptom, with recurring attacks of bilious vomiting. These, in a patient of visceroptotic build, are very suggestive, and the diagnosis is greatly helped if the symptoms are relieved by the adoption of the prone or genupectoral position. The association of migraine with the condition has attracted the attention of many writers. Obviously, the ultimate diagnosis depends upon the radiographic demonstration of a very dilated actively contracting duodenum, often with a "mosaic" pattern of the mucosa. Treatment of chronic duodenal ileus must of necessity vary with the cause. In the milder visceroptotic cases rest in recumbency followed by postural training and the use of a suitable belt will bring about a symptomatic cure. For the majority of cases, however, Wilkie believed that operative treatment is advisable. Since the cause of the obstruction can but rarely be relieved most surgeons rely upon a short-circuiting by anastomosing the dilated duodenum to the first loop of jejunum. This operation was performed upon 127 cases in this series; in thirty-eight the operation was combined with some other procedure such as gastro-enterostomy, gastro-duodenostomy, etc. The mortality rate of the operation was between 6 and 7 per cent. Operative treatment "gave on the whole a gratifying impression." Reading between the lines one gets the feeling that the results in the really pronounced cases were excellent, but that, as would be expected, in cases where the diagnosis was not so well established the results were correspondingly doubtful. This is in accord with experience in other branches of abdominal surgery, and is a point to which insufficient attention is paid in assessing the value of various operations. It has not escaped Wilkie's notice, for he wisely remarks that after initial successes in marked cases there is a tendency to try any new treatment in "less pronounced cases and in a number of doubtful examples when the early promise of success is not fulfilled. . . . The surgeon thus becomes more discriminating and critical in the selection of his cases. . . ." If the article contained no more than this penetrating commentary on surgical philosophy it would be well worth most careful study; as it is, it constitutes a memorial to Wilkie's pioneer work in this particular field.

THE UNITED KINGDOM AND THE DRUG TRAFFIC

The report of H.M. Government to the League of Nations on the traffic in opium and other dangerous drugs for the year 1937 might serve as a model for some other Governments which are parties to the several conventions. It follows the now familiar lines dealing with the administration nationally and internationally, with the Conventions of 1912, 1925, and 1931, with illicit traffic, and with addiction. The assurance is repeated that "addiction to narcotic drugs is not prevalent in the United Kingdom." The known addicts number 620, 300 men and 320 women; of the total 132 were medical practitioners, five were pharmacists, two were veterinary surgeons, and one was a dentist. In 72 per cent. of the cases morphine was the drug of addiction, in 17 per cent. heroin, and in 8½ per cent.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

ACUTE INFECTIONS OF THE BREAST

BY

CHARLES DONALD, Ch.M., F.R.C.S.

The ideal management of any disease is its prevention. Acute mastitis and its possible sequel, acute mammary abscess, occurring in the period of lactation, are often preceded by conditions the suitable treatment of which may have a preventive effect. Lack of care of the nipples in the later weeks of pregnancy and during lactation, inadequate treatment of a cracked or sore nipple, and failure to prevent stasis within the breast may all contribute to the production of those infections; but it should be added that in spite of every care they may occur, sometimes in epidemic-like form in institutions.

While such infections may occur apart from lactation, the great majority arise during that period, and it is these which will be considered here. The infection is associated with a cracked or sore nipple in probably less than half the cases. In the others it is presumed usually to have passed directly along the milk ducts from the nipple. It may be that infection has been blood-borne in some instances. The *Staphylococcus aureus* is the usual organism found—far less commonly the streptococcus. While the organism may gain access through it, a cracked or sore nipple is of much greater importance in that stasis occurs, because of the mother's inability to allow suckling on account of the pain. The retained milk then provides a suitable medium for the multiplication of organisms.

Cleanliness of the nipples, the avoidance of cracks and sores, their efficient treatment if they occur, and, above all, avoidance of stasis within the breast, then, are all of prime importance in the prevention of conditions which, if rarely dangerous to the life of the mother, are productive of much pain and discomfort, are a source of keen disappointment, and may have lasting effects on the health of the child. Efficient prophylaxis requires unremitting care on the part of the mother, the nurse, and the medical attendant.

Care of the Breasts in Pregnancy and During Lactation

Obstetricians are divided in opinion on the need for active treatment of normal nipples in preparation for pregnancy. Some consider that any such treatment is useless; others advise that in the last few weeks the mother should draw them out and cleanse them with soap and water twice daily, and massage them between thumb and forefinger with a little lubricant such as lanolin. The fashion of hardening the nipples with spirit or spirituous preparations has been falling into disuse as likely to favour the occurrence of cracks. The depressed nipple must of course be drawn out, and it is well treated by the measures related; but if for nothing else than instilling in the mother's mind the need for scrupulous cleanliness which will be required in the puerperium, it seems sensible to advise washing with soap and water twice daily during the last few weeks of pregnancy.

By far the greater number of breast infections occur in the first few weeks after parturition. A drill-like routine in the matter of cleanliness is required, therefore, right

from the outset. Before feeds the mother should thoroughly cleanse her hands in soap and water, paying particular attention to the finger-nails, which should be kept short. The nipples should be washed with warm boracic solution and care taken that neither nightdress nor bedclothes touch them. After the feed they are again washed with the solution, thoroughly dried, and covered with a piece of sterile gauze or gamgee pad held in position by the breast binder.

Night and morning in these first weeks the nurse should inspect the breasts with a view to the early detection of such conditions as may favour infection, since by their adequate early treatment such may be avoided. Any residual milk after feeds should be expressed manually or by the breast pump. Such a procedure prevents blockage of ducts with consequent future stasis. Again, the appearance of a cracked or sore nipple calls for immediate attention. The application of cold cream or of glycerin and borax in conjunction with the use of a nipple shield usually suffices to heal this condition. If stronger measures are needed, the application of a little friars' balsam effects a cure in most cases. A nipple shield should be employed where there is pain on suckling, whether a lesion be visible or not. Nipple shields should preferably be of the all-rubber type: glass shields tend to constrict the erectile nipple. As has already been said, not only is there the danger of infection passing by means of the crack, but the pain on suckling usually results in inefficient emptying, and therefore even more thorough precautions must be taken to express residual milk. Should the pain be too great to allow of suckling even with a nipple shield, direct feeding from that breast should be temporarily suspended, the milk being removed by manual expression by the mother and fed to the child through a bottle. Later, direct feeding is resumed.

Occasionally the nurse's inspection will reveal hardened tender nodules in the breast unaccompanied by any great constitutional disturbance. These are probably small areas of retention, and because of the possibility of their becoming foci of infection they require treatment. The breast should be completely emptied after each feed, manually or by breast pump. Light massage, working from the base of the breasts up to the nipple, should follow, the idea being to free any blocked ducts. Between feeds the breast should be supported in a raised position by brassière or bandage.

Acute Engorgement and "Breast Flush"

Two conditions occurring in the early puerperium require mention because of the necessity for differentiating them from acute pyogenic conditions. The physiological milk engorgement of the breast which takes place about the fourth or fifth day may in some patients, particularly elderly primiparae, be so severe in symptoms and signs as to suggest acute inflammation. The breasts are tense and flushed, with pronounced veining, there is a transient rise of temperature and the patient feels "seedy." Relief is afforded by the use of a saline aperient night and morning and the use of a breast pump after the feed; in persistent cases fomentations will help.

About the tenth day there may occur what is known as a "breast flush." This is a sector- or quadrant-shaped

flush of the surface of the breast accompanied by marked constitutional disturbance. The patient often expresses the idea that she is going to have influenza. Starting commonly with a rigor, the temperature reaches 103° to 104° F. The breast is hot rather than tender, and there is no underlying induration of the sector. Most important of all, little breast pain is complained of. "Breast flush" only very rarely passes on to suppuration, and usually subsides in forty-eight hours. It is regarded by some as streptococcal in nature, and by them treated with 15 grains of sulphonamide eight-hourly. By others it is regarded as a local acute engorgement. There is no need to use fomentations, and these conceivably might tend to produce suppuration.

Acute Mastitis

Human breast milk in a proportion of cases contains organisms, not infrequently the *Staphylococcus aureus*. Any condition of stagnation, therefore, will offer a chance of multiplication of these organisms. Such stagnation may occur by the blocking of ducts from inspissated milk. Stagnation, again, may be the result of the inflammation of the wall of a duct or ducts by organisms that have gained entrance by the nipple. A local engorgement is thus the forerunner of an acute mastitis, and there is no clear dividing-line between the two. Severe pain within the breast, often preceded by a shiver or rigor, is the most characteristic early symptom. The breast is tender, locally or diffusely. In the case associated with a cracked nipple a lump is usually palpable early—not always so in other cases. About twelve hours after the onset of pain a cellulitic appearance of the breast, local or diffuse, appears. The temperature is raised and keeps swinging up to about 100° F.

At this stage attempts to aid resolution constitute the line of treatment. The application of heat by antiphlogistine or linseed poultices, leaving the nipple clear, is

The tight figure-of-8 bandage.

helpful and comforting. Any attempt at massage now is contraindicated. The child may still be suckled unless pain be caused, but the breast pump should be employed to extract any more milk possible. Resolution may then be accomplished.

Where the symptoms become more severe in spite of treatment, it is likely that the condition is to pass on to abscess-formation. The application of large fomentations

should now be employed to aid the process of localization. The vexed question of whether or not to wean the child then arises. There is no doubt that infection subsides much more quickly after weaning, and therefore in severe and moderately severe cases this should be done. There are, at the other extreme, mild cases in which feeding may still be carried on from one or both breasts. If the affected one is not used, the milk is extracted by the breast pump. Each case must be considered on its merits. The mother's milk is the best for the child, and there are economic considerations against its lightly being abandoned. Weaning is satisfactorily accomplished by the use of magnesium sulphate crystals, a tablespoonful each morning in half a glass of warm water, followed by hot tea. There is no need to diminish the intake of fluids. A supporting dressing is applied to the breast. This is well accomplished by a figure-of-8 five-inch calico bandage, running over both breasts but not over the shoulders, put on while the arms are extended above the head. This bandage should be applied so tightly as to make the patient complain of slight constriction of the chest (see figure). The amount of magnesium sulphate crystals is gradually diminished. Weaning should thus be satisfactorily accomplished within a week.

Acute Mammary Abscess

Although it is usual to describe three types of acute breast abscess—the subareolar, the intramammary, and the retromammary—the intramammary is by far the commonest and most important. The retromammary form in lactation is almost invariably secondary to a deep intramammary abscess: its importance, apart from lactation, is concerned with its differential diagnosis from abscesses arising in the breast wall. The subareolar abscess is a small superficial collection unrelated to any deep process, and fluctuation and the time for a small incision are early determined.

What is the correct time for incision of an intramammary abscess? There is no doubt that many, possibly the majority, are prematurely incised. The temptation to insert a knife into any cellulitic area seems irresistible to some people. Incisions in the various forms of milk engorgement and acute mastitis are a disappointment to both patient and doctor. This practice, often associated with the making of counter-incisions for so-called dependent drainage, is utterly to be condemned. Not only is further incision likely to be needed later, but by cutting through normal breast tissue in making counter-incisions the infective process at this diffuse stage is allowed to spread further afield. A well-localized acute abscess opened fully by a single incision at a point nearest the surface, whatever its position in the breast, will discharge its contents freely without the need for counter-incision. (The latter should be reserved for the very rare cases which go on to a sort of chronic diffuse suppuration throughout the breast.)

In the determination of the optimum time for incision let it be said that there is little hurry. It is not a matter only of being sure, from the symptoms and signs, that pus is present: pus may be formed at several points in the involved area. Given time, these will coalesce and tend to form an abscess which, although loculated, is only poorly so, and which can be dealt with thoroughly through a single incision. By daily inspection of the breast it will be seen that in the average case the cellulitic appearance of the skin lessens and becomes more circumscribed, in some deep cases practically disappearing. The underlying indurated area gradually becomes more defined

and somewhat spherical in shape. Where the abscess is not situated very deeply the overlying skin begins to become a more pronounced red and to pit on pressure. This—and it may take a week or more—is the time for incision. Left a little longer the pus would burrow through the covering fascia of the breast and point on the surface as the smaller portion of a collar-stud abscess. There is no need to wait for this. Where, however, the abscess is situated deeply, apart from an actual retro-mammary abscess, the time for incision is not so obvious. The pus, however, tends to gravitate to the apex of the breast, and in time a break in the fascia underneath the corresponding segment of the areola can be felt by the tip of the finger. This is the premonitor of a collar-stud abscess, and an incision at this time will allow complete evacuation.

Incisions into the breast should be radial from the nipple over the swelling. Much has been needlessly written on the subject of planning incisions for cosmetic effect. The ordinary radial incision made at the right time leaves surprisingly little trace. The operation is easily carried out under gas or gas-and-oxygen anaesthesia. The length of the incision will vary in different cases, but it should always be ample. After the abscess has been incised, a finger is introduced and free communication established between the loculi, which, if the proper time has been allowed to elapse, are already communicating. No undue force should be employed in doing this. Stout strands passing across the cavity should not be torn, for within them are intact ducts and blood vessels; and the breasts should not be squeezed roughly. A drain is now introduced. This is best made of soft corrugated rubber dam or rubber glove material. Where the child has been weaned it is not desirable to use rubber tubes (and indeed they should never be necessary), since the figure-of-8 bandage could not be applied tightly enough. This bandage, over gauze and wool, obviates also any need for packing the wound on account of haemorrhage, which, however, should not occur to any alarming extent if the abscess has been opened at the right time. Assuming still that the child has been weaned, this tight bandage should not be moved for forty-eight hours, and subsequent dressings, except in cases with very copious drainage, should be done at the same interval. The glove drain is removed at the first dressing. Irrigation with antiseptics is unnecessary. When the child has not been weaned and the condition does not clear up readily, weaning is usually followed by rapid cure.

After constitutional symptoms have abated the patient should be kept in bed until progressive healing is taking place. Ambulatory treatment, except in the mildest of cases, is unsatisfactory and prolongs convalescence.

There are rare forms of acute pyogenic infection in which either the whole breast becomes the seat of diffuse suppuration or there is a slow-spreading cellulitis which keeps breaking down at various points. Such conditions require the full scope of hospital treatment, and need not be considered here.

O. W. H. Mitchell, T. L. Bryant, and O. D. Chapman (N.Y. *St. J. Med.*, 1938, 38, 1022) record 135 cases of gas gangrene which occurred in New York State, exclusive of New York City, in the years 1932 to 1936 inclusive. The predisposing factors were as follows: trauma ninety-one, clean amputations thirteen, pregnancy seven, gunshot wounds five, and miscellaneous nineteen. Eighty-four patients were treated with specific serum (*perfringens* antitoxin) with twenty-nine deaths, and fifty-one without serum with thirty-five deaths:

GROUP PSYCHOLOGY AND SOCIAL POLICY

[FROM A CORRESPONDENT]

The era which has seen the greatest advances in medicine has witnessed two highly significant social trends. In economic life the old cohesion of groups has broken down, leading to more individualistic behaviour and greater mobility of labour. At the same time, medicine has learnt to serve the individual by studying the needs of the group to which he belongs. Both tendencies have worked to form a somewhat impersonal attitude towards the motivations behind social life. No one will deny that man is wise to seek the highest economic status open to him or that money is an urgent incentive, but there is something more. Professor E. P. Cathcart recently referred to "malnutrition of the spirit." This is no sentimental evasion but rather a profound and neglected truth.

"There is a social motive in economic activity so that routine which first develops as a technical convenience grows into stable custom and becomes shot through with sentiment." These sentiments have been analysed by Professor T. North Whitehead of Harvard,¹ and the conclusions he reaches are of considerable importance at a time when social and economic custom the world over is literally in the melting-pot. You cannot break up social groupings in factories or industrial areas, you cannot remove skilled men into new environments, and you cannot play fast and loose with the inner disciplines of established forms of life solely for financial or economic ends without grave risk unless a vital prophylaxis is established. There must be a new form of emotional satisfaction ready to take the strain the moment the old ties are slackened or broken unless there be a continuity of emotional satisfaction over and above these. Medicine, which has with such success studied the group needs of man in regard to physical hazards, has failed, however, to take full account of these aspects of group psychology, with a result that much of the individual emotional disturbance of men and women is incompletely diagnosed.

Spiritual and Emotional Unity

Professor Whitehead has much to say on group ways and sentiments, and though it is addressed mainly to industrial administrators it would be well if doctors and statesmen paid heed to his advice. He makes it clear that a financial and an emotional incentive are necessary for healthy and effective work, and that it is no use strengthening the former at the expense of the latter unless we wish to produce serious imbalance and breakdown in social and economic life. It is no secret that democracy has given such rein to free economic development that the financial aspect of industrial life has run away with itself, and that, whether we like it or not, certain other forms of government have concentrated on giving scope for an overriding emotional outlet which has offset to a large extent the discontents that would otherwise have become manifest. Hence we find our own statesmen suddenly waking up to a realization that some form of spiritual or emotional unity is necessary in this country: something which will hold men and women on their course, despite breaks in their more immediate personal systems; something which will cause them to hope and live for a greater end than that which lies close to them. If this unity is

¹ *Occupational Psychology*. Vol. xii, No. 4, Autumn, 1937. National Institute of Industrial Psychology, Aldwych House, London, W.C.2. 5s.

to be attained by mass hysteria, war preparedness, or fear it may last for a time, but the reaction will be terrible. We have not got a deep slough of despond as formerly existed in Germany, a sense of national inferiority such as preceded Mussolini in Italy, or a vast social chaos as in post-war Russia, to act as the spur to effort or as the focus of emotion. Our problem is more complex. With a relatively high standard of living, a great degree of personal freedom both to serve and to exploit, and a sense of greatness as a people, we find also a disillusionment regarding the use we have made of our opportunities, a bewilderment at the blots on the fitness of large sections of our people, and a realization that too many people are playing with the tokens of life and too few concentrating on the supply of real satisfactions. What spirit can we create to unify our people without loss of individuality, to vitalize all our social services, to give scope and satisfaction to the young, and to guide our relations abroad in the light of biological truth?

National Health and Fitness

We shall not raise our standard of health and fitness by the methods of the recruiting sergeant or by emotional appeals which ignore realities. The only method, and it is to be hoped our statesmen will realize it, is to stop financial exploitation, to produce goods and to supply services because they are needed and not solely for profit, to suppress waste of life and labour, and to let youth see that their welfare is the prime concern of the State, that their labour is used for the welfare of the whole, and that their basic physical and mental needs are going to be met at all costs. Remembering that rights and duties coexist, they will in return be expected to give of their best; but before the demands are made we must know why we make them and see that our policy at home and abroad is directed biologically in such a way that sectional interests shall not under any guise be allowed to divert national aims from the goal of a happy, peaceful, and productive world.

THE STATE OF THE PUBLIC HEALTH

SIR ARTHUR MacNALT'S REPORT

The nineteenth Annual Report of the Chief Medical Officer of the Ministry of Health, Sir Arthur MacNalty, for the year 1937 was published on October 31.* It is a composite document, the work of many hands, and gives an account of the main aspects of the work undertaken by the seven sections into which the Medical Department is subdivided.

Specialist Services and Health

The report opens with a review of specialist services in their relation to the public health. An account is given of the historical development of specialism in England, the present provision of specialist services by local authorities and at voluntary hospitals is reviewed, and the need for co-ordination and integration of the existing services stressed. Consideration is also given to developments which could reasonably be undertaken by local authorities, with the aid of voluntary hospitals, to provide more specialist advice and treatment in the areas for which they are responsible. Finally, it is claimed that, in spite of the present financial stringency, "much of this co-ordination, integration, and development could be effected by wise administration and good will with little expenditure of public money."

* H.M. Stationery Office, price 3s. 6d.

Vital Statistics

Last year there was a rise of 5,265 births over the number registered in 1936, representing a birth rate of 14.9 per 1,000 living—a slight improvement on the rate of 14.8 for 1936. It is 0.5 above the rate for 1933, which was the lowest recorded, though it is only 0.1 above that for 1934. The infant mortality rate is 58 per 1,000 births, as against 59 for 1936, though it is still one point higher than the exceptionally low figure of 57 reached in 1935. The deaths in 1937 were 509,574, compared with 495,764 in 1936, an increase of 13,810. The five principal killing diseases remain the same as for many years past and occur in the same order:

- (1) Diseases of the heart and circulatory system.
- (2) Cancer—malignant disease.
- (3) Bronchitis, pneumonia, and other respiratory diseases.
- (4) Diseases of the nervous system.
- (5) All forms of tuberculosis.

If, however, the diseases are rearranged to show the principal killing diseases operating during the years of working life—15 to 65—then tuberculosis takes the third place instead of the fifth and diseases of the nervous system occupy the fifth place. The chapter includes statistical reviews of the trend of mortality in childhood and in old age.

Maternity and Child Welfare

The maternal mortality rate per 1,000 total births continues to fall, being 3.13, compared with 3.65 for 1936, 3.94 for 1935, and 4.41 for 1934. Puerperal sepsis accounted for 0.94 per 1,000, leaving 2.19 for other causes. The rates from both puerperal sepsis and other puerperal causes have shared in the fall, but in each year the greater reduction has been in the rate for puerperal sepsis. The rate expressed per 1,000 live births which admits of comparison with each year from 1911, when the present classification was introduced, was 3.26 in 1937, and is the lowest rate recorded during that period of twenty-seven years. The following table extracted from the tabular maternal mortality statistics shows year by year the maternal death rates per 1,000 total births (live and still births) from the year 1928, when stillbirths first became registrable.

Year	Puerperal Sepsis	Other Puerperal Causes	Total Puerperal Mortality	Non-puerperal Causes	Total Maternal Mortality
1928	1.72	2.52	4.25	1.15	5.39
1929	1.73	2.43	4.16	1.43	5.59
1930	1.84	2.38	4.22	1.14	5.36
1931	1.59	2.35	3.95	1.38	5.32
1932	1.55	2.49	4.04	1.11	5.15
1933	1.75	2.57	4.32	1.37	5.69
1934	1.95	2.47	4.41	1.20	5.61
1935	1.61	2.32	3.94	1.14	5.08
1936	1.34	2.31	3.65	1.06	4.71
1937	0.94	2.19	3.13	1.19	4.32

A summary is given of confidential reports on individual maternal deaths. The Interdepartmental Committee set up by the Minister of Health and the Home Secretary to inquire into the prevalence of abortion and prevention of deaths from this cause is still deliberating. An account is given of the progress of schemes under the Midwives Act, 1936, and of the Rules now framed by the Central Midwives Board under Section 7 (1) of this Act.

Among other matters dealt with in this chapter of the report may be mentioned investigations into puerperal sepsis, recent research on the treatment of puerperal fever by sulphanilamide, and an account of child welfare

activities. Increasing difficulties in meeting the demand for trained nurses and allegations of unsatisfactory conditions of service, etc., led the Minister of Health and the President of the Board of Education to set up an Inter-departmental Committee on the Nursing Services to investigate this important and complicated problem. The chapter ends with an account of the maternity and child welfare services in Wales.

Epidemic Diseases

On a general review there has been a decline in the incidence of encephalitis lethargica and scarlet fever, and a slight decrease in both the incidence of enteric fever and the number of deaths from the disease, though both these figures are appreciably higher than in 1935. For the comparatively small decline in enteric fever incidence and fatality the outbreaks of typhoid at Croydon and paratyphoid at Liverpool, Bootle, and the surrounding district are mainly responsible. On the other hand there has been a rise in the incidence of cerebrospinal fever, diphtheria, dysentery, acute influenzal pneumonia, acute poliomyelitis, and acute polio-encephalitis. In respect of these and some other infectious diseases further details are as follows:

Scarlet Fever and Other Streptococcal Infections.—In 1937 there were 95,737 notifications of scarlet fever with 349 deaths, as against 104,862 notifications and 495 deaths in 1936.

Enteric Fever.—During the year there were (including paratyphoid fever) 2,151 notifications with 206 deaths—a mortality of 9.6 per cent. For 1936 the corresponding figures were 2,490 with 257 deaths and for 1935 1,750 cases with 174 deaths. An account is given of the Liverpool and Croydon outbreaks.

Influenza.—The total number of influenzal deaths was 18,635, of which a large proportion occurred, as is usual, in the first quarter of the year. The heavy death roll was, however, due to excessive prevalence and not to any increase of virulence in the type of the infection. The point is made that remarkable waves of notified pneumonia have followed upon modern epidemics of influenza, and these waves have neither been accompanied nor followed by serious mortality from influenza. This phenomenon accompanied the epidemic of 1937.

Diphtheria.—Of this disease 61,339 cases were notified, with 2,963 deaths—a fatality rate of 4.8 per cent.—as compared with 57,795 cases in 1936 and a fatality rate of 5.3 per cent.

Other Epidemic Diseases.—In 1937 there were notified 4 cases of small-pox—3 variola major and 1 variola minor. There were no deaths. The notifications for the three preceding years were 12, 1, and 179 respectively. Five cases of post-vaccinal encephalitis were reported in 1937 and there were five in 1936. The number of cases of dysentery notified during 1937 was 4,167, as against 1,333 in 1936. A proportion of the increase is believed to be due to better diagnosis and more care in notification of the Sonne type, but a completely satisfactory explanation is lacking. The number of deaths from whooping-cough was 1,750, as compared with 2,090 in the preceding year. The evidence as to the value of vaccines in this disease is conflicting. A substantial rise in the incidence of poliomyelitis and polio-encephalitis occurred in 1937, but the fall in the notifications of encephalitis lethargica continues. The notifications of cerebrospinal fever have again increased a little over those for 1936, the figures being 1,140 and 994 respectively. Though the incidence has not decreased, the total number of deaths from puerperal sepsis and puerperal pyrexia shows a notable decline from 843 in 1936 to 596 in 1937. Three suspected cases of psittacosis were reported to the Ministry in 1937, but one was finally shown to be due to another cause, and the diagnosis of the other two remains in some doubt. No case of malaria acquired in England and Wales was recorded during the year.

The Insurance Medical Service

Two important innovations were made during 1937. The first was that the medical benefits of national health insurance were extended to cover all young persons over

the school-leaving age who become insurably employed, thus closing the gap which had existed between the medical supervision afforded by the School Medical Service and that available under the Insurance Medical Service, which hitherto only became effective in the case of persons of 16 years of age and upwards. The second was a great extension of the scheme of postgraduate courses for medical practitioners. Under this larger scheme, which will apply to practitioners irrespective of where they practise, it is intended that they shall be able to obtain a free course once in every five years. Within specified limits, not only will the course fee be paid, but also travelling and subsistence costs and the cost of a whole-time locum tenent where one is required.

In 1937 the number of insured persons entitled to medical benefit in England and Wales was 17,032,000 and the number of insurance practitioners was 16,800—increases of 712,000 and 50 on the previous year. The total cost of medical benefit, exclusive of cost of administration, was £10,436,000, of which £7,914,400 represented the doctors' remuneration and £2,521,600 the cost of medicines and appliances. The sum of £2,448,000 was expended from the disposable surplus of approved societies for additional treatment benefits in 1937 in England alone, of which additional benefits the most important are dental and ophthalmic benefits.

Water Supplies and Disease

This country has long enjoyed relative immunity from serious outbreaks of water-borne disease. An account of the outbreaks which have occurred since 1911 emphasizes the serious responsibility which rests upon the various authorities concerned and the need for maintaining the utmost vigilance to prevent any breakdown in the defences. Stress is laid upon the necessity for protecting water supplies derived from chalk or similarly fissured strata, especially in areas where building in the vicinity of waterworks has increased since the time when the wells were originally sunk. Advice is given respecting the measures desirable to attain and safeguard the purity of supply.

(To be concluded)

CONGRESS OF COMPARATIVE PATHOLOGY, ROME, MAY, 1939

The fourth International Congress of Comparative Pathology, which is to be held in Rome from May 15 to 20, 1939, promises to be of special interest. Professor Rondani, Member of the Royal Academy of Italy and Director of the Cancer Institute at the University of Milan, will be its President, and already about twenty rapporteurs have been chosen for the following subjects:

- Ultravirus diseases.
- Heredity in pathology.
- The association of antigens and their function.
- Regressive processes in plants.

The British rapporteurs include Professor F. A. E. Crew on heredity in pathology, and Professor J. R. Marrack on antigens. The Congress Committee will be glad to receive shorter communications on any of the above-named subjects not later than March 31, 1939. The Secretary of the Congress is Professor Zavagli, to whom such communications should be sent, addressing them to him at Consiglio Nazionale delle Ricerche, Piazzale delle Scienze, Rome.

The membership subscription is 250 lire, or in English money £2 12s. 6d. This subscription gives the right to reduced rates granted by the railways, shipping companies, and hotels; to participate in all excursions and ceremonies, including the banquet, and to receive the general reports of the Congress. The ladies' subscription is 100 lire (£1 1s.). Subscriptions may be sent to the Secretary of the British National Committee, Dr. Fred Bullock, at 9, Red Lion Square, London, W.C.1, who will undertake to pass them on to the Secretary in Rome. The last date for the reception of subscriptions by the Rome Secretariat is March 31, 1939.

EXTENSION OF INCOME TAX ALLOWANCE FOR CHILDREN

It is a matter of common knowledge that though the allowance for a child normally ceases when the child attains the age of 16, it is continued while the "child" receives whole-time instruction at a recognized educational establishment. This usually covers the case of a "child" who is receiving training at a hospital, but hitherto has not applied to training as an articulated pupil or an apprentice. During one of the later stages of this year's Finance Bill, however, the Chancellor of the Exchequer added another concession, intended primarily, it would seem, to meet the case of an apprentice, but in fact having a somewhat wider scope. The concession is embodied in Section 20 of the Finance Act, 1938, and the possibility of relief under that provision might well be borne in mind in connexion with the notices of assessment to tax which are now reaching the hands of our readers.

The old relief is now extended to include "a child undergoing training by any person for any trade, profession, or vocation," but this extension is subject to two conditions. The first is that the child is required to devote the whole of his time to the training for a period of not less than two years, and the other is that during the period of training the emoluments of the child do not exceed £13 a year. There is provision for setting off the amount of the premium paid in respect of the training from the emoluments payable by the employer. The net effect is to give the child allowance in cases where the ordinary education has ceased and the child is receiving technical training under apprenticeship indentures or articles—for example, as an articulated clerk to a solicitor or accountant. As the allowance represents tax on £60—that is, £16 10s. at the present standard rate of 5s. 6d. in the £—the relief is not insubstantial. Medical practitioners who have a child coming within the extended relief should communicate with the local Inspector of Taxes requesting him to supply them with the appropriate form of claim.

RESEARCH FELLOWSHIPS IN TROPICAL MEDICINE

The Medical Research Council, on the advice of its Tropical Medical Research Committee, has awarded the following Junior Fellowships:

SCOTT GLADSTONE COWPER, B.Sc., Ph.D., M.R.C.S., L.R.C.P.

ALEXANDER JOHN HADDOW, M.B., B.Sc.

WILLIAM HEPBURN RUSSELL LUMSDEN, M.B., B.Sc.

These Fellowships are tenable for three years, during the first two of which the holders will undergo training in this country in tropical medicine and in the use of research methods.

The Premio Alvarenga do Piahy (Brazil) Prize for 1939, about 200 dollars, will be conferred by the College of Physicians of Philadelphia on July 14, 1939, upon the author either of the best memorial or of the best unpublished essay on any branch of medicine which may be deemed worthy of the prize. In selecting the winner of the award the committee will consider recent publications brought to its attention prior to May 1, 1939; also unpublished typewritten manuscripts submitted before that date. Manuscripts not in English must be accompanied by a translation in English. Communications should be addressed to the Alvarenga Prize Committee, 19, South Twenty-second Street, Philadelphia, Pennsylvania, U.S.A.

Reports of Societies

UTERINE INERTIA

Blair-Bell Memorial Lecture

Among the benefactions of which the British College of Obstetricians and Gynaecologists became possessed under the will of its first President, the late Professor Blair-Bell, was the foundation of a lectureship. The first William Blair-Bell Lecture was delivered at the College on October 28 by Mr. T. M. A. JEFFCOATE of Liverpool, who took as his subject uterine inertia.

Mr. Jeffcoate said that the subject of uterine inertia was one in which Blair-Bell himself was particularly interested. His views were at variance with those of most of the obstetricians of his period, but they were now coming to be more and more accepted, although in a modified form. Blair-Bell considered that uterine inertia, whether primary or secondary, was for the most part caused by a deficiency of pressor substances in the blood stream. Later he included oestrogenic substances with the pressor substances.

A study of the treatment of uterine inertia demanded a knowledge of the normal physiology of the uterus and of the factors which ordinarily controlled it. The oestrogenic hormones had a share in the control of its contractions, passivity, and tone. As pregnancy advanced the amount of oestrogenic hormone in the circulation increased, and during the period immediately preceding labour it became activated and free to exert its full biological effect. When the uterus was fully sensitized by the oestrogenic hormone any minor stimulus might be sufficient to cause the onset of labour. It was logical to assume that the factors bringing about expulsive contractions were of assistance also during labour itself. The nature of the uterine contraction and the progress of cervical dilatation were largely dependent upon the relation between the passages and the "passenger." Endogenous factors were a first concern in the preparation of the uterus during pregnancy and also for the onset and maintenance of the expulsive uterine contractions, and here the oestrogenic hormone was of great importance. In animals this hormone was the only substance known that would stimulate an inactive uterus.

A Clinical Investigation

In view of these considerations it was decided to carry out a clinical investigation of patients treated for inertia with oestrogenic hormones. Emotional disturbances were often concerned in the aetiology of inertia, and any method of treatment might improve uterine action solely by means of its psychological effect. It was therefore always difficult to assess the results and difficult also to ascertain in all cases the exact time of onset of labour. In this trial, however, the utmost precautions were taken, only cases of inertia of long standing and characterized by complete or almost complete cessation of pains being selected. Only eighty-eight cases suitable for treatment were encountered in a series of many hundreds of confinements, and the duration of uterine contractions and the interval between them were charted before, during, and after treatment. Various oestrogenic hormone preparations were employed, but mostly oestrone benzoate in 2 mg. doses in an oily medium. This was administered intramuscularly and, with few exceptions, at one-hour intervals, continuing for eight to ten hours unless delivery was completed before the end of that time. The results are shown in the table on the next page.

There were sixty-seven primary cases, thirty of them complicated and thirty-seven uncomplicated; twenty-one secondary cases, seven of them complicated and fourteen uncomplicated; and successful results were reported in fifty. The mechanical fault with which inertia was com-

plicated was in twenty-two of the thirty-seven cases malposition or malrotation of the head. Among the successful cases nineteen had instrumental delivery and four Caesarean section, the other twenty-seven being delivered

Results of Treatment of Uterine Inertia by Oestrogenic Hormones

by natural forces. Of the cases in which treatment was unsuccessful, eighteen had instrumental delivery and five Caesarean section.

The cases required further analysis from the point of view of the aetiology of the inertia. There was no theoretical or practical reason for regarding primary and secondary inertia as separate clinical entities, and it was often impossible in practice to say whether the inertia was primary or secondary. As alternative terms the first stage and second stage of labour were preferable. Of the eighty-eight cases, seventy-four showed inertia in the first stage, and forty-two successful results were achieved; fourteen showed inertia in the second stage, with eight successful results.

The response to oestrogenic treatment bore no relation to the time of onset of inertia, nor to the stage of labour at which the treatment was started. This offered further support to the belief that inertia was a single clinical entity, though it might make its appearance at different stages in parturition. It seemed permissible to state that the treatment was free from risk to either mother or child. In some of the later cases tests were made using an aqueous rather than an oily medium, but the results showed very little difference.

Prophylactic Treatment

Prophylactic treatment had been tried in another series of fifty-one patients in all of whom some abnormality was present or there was a definite reason for supposing that labour would be difficult. In these cases 2 mg. of the hormone substance was injected at intervals of from one to twelve hours for periods of from one to twenty-one days before delivery. The best results followed administration at eight- or twelve-hourly intervals for four days or longer. Of these fifty-one patients only three developed inertia in labour. The average duration of the labour in the twenty-one primigravidae was 15.6 hours, and in the multiparae 9.7 hours, leaving out of account six cases in which the duration of labour was unknown. There were four instrumental deliveries in this series and two Caesarean sections.

One deduction from this work was that it was the middle-aged woman with a large family, however much burdened by domestic cares, who had usually the uncomplicated and easy labour, and the primigravidae who were particularly the subjects of inertia, especially those over the age of 30. Again, it was the athletic woman rather than the effeminate who was likely to have disordered uterine action.

Twin Pregnancies

He had also investigated 100 cases of twin pregnancy—forty-four primigravidae and fifty-six multiparae. The average duration of labour was well within normal limits, as the following table showed:

Average Duration of Labour

	First Stage Hours	Second Stage Hours	Total Duration Hours
Primigravidae ..	12.3	2.5	15.1
Multiparae	7.8	1.1	9.1

Five of the original eighty-eight cases were also of multiple pregnancy. Thus the conception that overdistension of the uterus did not directly produce inertia was borne out.

It would be wrong, Mr. Jeffcoate concluded, to omit reference to emotional factors, of which fear was the most important. Emotional causes were as far as possible excluded from the series under discussion, but he did not wish to diminish the importance of administering morphine and other sedatives. Inertia was a wide subject, and it had been necessary to confine the lecture to a few of its aspects. He was of opinion that oestrogenic hormones should be used where the uterine inertia was not improved by sedatives and anti-spasmodics. They served to regulate and co-ordinate the uterine contractions. The endocrinological viewpoint of uterine inertia was intriguing and one in which investigation had only just started, but it was clearly not the only important aspect of the subject, the mechanical relationship being also of considerable account for any patient exhibiting feeble or irregular uterine contractions in labour.

BENZEDRINE: USES AND ABUSES

A combined meeting of the Sections of Medicine and of Therapeutics and Pharmacology of the Royal Society of Medicine was held on October 25, Dr. H. LETHEBY Tidy presiding, for a discussion on benzedrine, its uses and abuses. Dr. Tidy said that benzedrine, a synthetic drug allied chemically to ephedrine, illustrated the new tendency for pharmacological discoveries to have more in them than was originally claimed. In the old days a drug was put upon the market with a thousand indications in the hope that some more or less accurate observer would report success in one of them; the process with some recent introductions had been the reverse.

Summary of Recent Experience

Dr. IVOR J. DAVIES (Cardiff Royal Infirmary) opened the discussion by referring to his review of the toxic effects of benzedrine which appeared in the *British Medical Journal* (1937, 2, 615). In that review he described the case of a student who administered benzedrine to himself (190 mg. in nineteen days) with the idea of equipping himself better for his examination. Severe aplastic anaemia resulted, together with failure in the examination. The student had now recovered and done well. He had informed him that the drug was a good deal used by students in these circumstances.

Dr. Davies went on to say that since the publication of that review he had had no further personal experiences, and could only comment on the physical effects observed recently by others. He referred to the work of Gwynne and Yater, who had studied the immediate effects of benzedrine sulphate in therapeutic doses on a large number of students, and who concluded that the use of the drug might be permitted or even prescribed for normal persons suffering from lack of self-confidence or mild depression who deemed it advisable to overcome these drawbacks temporarily, but they emphasized that such use of the drug should only be an emergency measure. The same workers considered that the drug was not habit-forming. Hill of the R.M.S. *Aquitania* had studied 100 cases of seasickness treated with benzedrine alone or combined with other remedies, and concluded that the drug had great possibilities of usefulness in certain cases of seasickness in which there were signs of excessive vague activity.

Boyd and others had studied the use of the drug in the relief of the common cold. It was found to relieve the symptoms resulting from nasal turgescence, but not to shorten the cold's duration. Davidoff and Reifstein, in studying some of the physiological effects of benzedrine sulphate, found them to be "variable, uncertain, unpredictable, and at times paradoxical." Detrick and others had studied the stimulant effect of the drug on the central nervous system, and Rosenberg had described its effects on the gastro-intestinal tract and its limitations in the treatment of the spastic colon. Of eighteen cases of spastic colon, three improved, one showed improvement followed by relapse, eleven were not improved, and three were made worse.

From January 1, 1939, the drug would be placed in the First Schedule of the Poisons Act. With all due respect to the Home Office and its advisers, he thought it should have been placed in the Fourth Schedule. Under the First Schedule, it was true, it could be obtained only by a doctor's prescription, but it could be repeated on the same prescription, whereas under the Fourth Schedule it could only be dispensed once.

Psychological Effects of Benzedrine

Dr. E. GUTMANN (Maudsley Hospital) also referred and added to the paper he, with W. Sargent, had contributed to the *British Medical Journal* (1937, 1, 1013). With regard to the effect of benzedrine on normal individuals, the difficulty was for the psychiatric inquirer to find such normals among the people with whom he commonly had to do. One psychological effect following the use of the drug with normal people was an alteration in the sense of time. The subjects said that time passed more quickly; the same time intervals when repeated seemed to be shorter. There was no evidence of sexual excitation. The effect of a single dose usually passed off within a day. The effects observed from continued administration of small doses were of the same kind, but of gradually weakened intensity. Myerson and his co-workers in the United States had reported no improvement under benzedrine in the cases in their psychiatric clinic, and said that fifteen out of eighty cases showed temporary accentuation of the psychosis. It was now generally agreed that benzedrine did not improve schizophrenic psychosis, also that severe depression and depressive stupors did not benefit, small doses having little or no effect, while large doses produced anxiety or untoward physical symptoms. The drug seemed to produce its best effects at the end of a depressive attack. He agreed with Myerson that the psychological effects with benzedrine were best produced by small doses. In most cases 2.5 mg., given two or three times during the morning, would yield better results than one large dose. The difficult cases were those of psychasthenia, seen in the type of person easily fatigued or exhausted. Addiction was rare. He had come across only one case of possible addiction, and he doubted whether that could properly be so described. It was the case of a woman who had taken 10 to 25 mg. daily for several months. At first she was so stimulated that her well-doing at work aroused the jealousy of her workmates, but toxic effects presently appeared. On coming to Maudsley she gave up the drug without much trouble, did not describe any deprivation symptoms, and never made an attempt to get a fresh supply.

Pharmacological Aspects

Dr. J. W. TREVAN said that benzedrine might be regarded as a derivative of the ephedrine series, nor-ephedrine differing from benzedrine in the replacement of a carbon atom in the side-chain of benzedrine by a hydroxyl group. In the form in clinical use it was a racemic mixture of *d*- and *l*-phenylisopropylamine, the end carbon atom being asymmetrically combined. It was first introduced for its vasoconstricting effect on the nasal mucosa. In animals it produced a rise in blood pressure

which was about the same as that produced by phenylethylamine, and, as with ephedrine, repetition of the dose produced a smaller effect. Doses of 50 mg. by mouth were followed by a rise of arterial blood pressure, which might last for some hours. It caused contraction of smooth muscle. Its action was not sympathomimetic, as its activity was not reversed by ergotoxin. It was extremely active in awakening animals from anaesthetic sleep; at least as active as coramine but less active than cardiazol or picrotoxin, but, unlike these, it did not at any dose produce clonic convulsions. It produced, however, a great increase in voluntary motor activity in mice. The experimental mice on recovering from the anaesthetic sleep showed perfectly co-ordinated motor activity, but carried out at something like twice the normal rate. When resolved the *d*-form was considerably more active than the *l*-form. Substitution of one hydrogen atom in the amino group by a methyl group increased the anaesthetic action in mice; substitution of both hydrogen atoms in the amino group destroyed this action. The determination of the anaesthetic activity of a drug as judged by the usual methods was very crude, but it seemed clear that the benzedrine group and the picrotoxin group acted by influencing different parts of the central nervous system, and it was possible that the awakening was brought about by the mediation of nervous stimuli originating for the benzedrine group in the cerebrum and for the picrotoxin group somewhere in the neighbourhood of the red nucleus. Where the stimuli originated for the ephedrines he could not say. Dr. RICHTER added a few words on the pharmacological properties of these amines of the benzedrine and ephedrine series. Instead of acid appearing in the urine the amine appeared to come out unchanged. Ephedrine was excreted a good deal faster than its fellow.

Addiction

Dr. G. RUDOLF said that he had used benzedrine in some fifty cases of mild depression, and it struck him quite forcibly that the patients who benefited most were those who were depressed in the early part of the day. If the patient were asked, "Are you depressed in the morning or evening?"—carefully accentuating the words "or evening"—and it was found that the depression was usually in the morning, benzedrine in almost every case brought about improvement. But it was necessary to start with small doses. The experience of one who had never previously taken the drug was that with 2.5 mg. he felt improved, but with 5 mg. he felt "drunk," though actually he walked straight. Dr. Rudolf knew one doctor who used the inhaler for a cold, applying it about once an hour, and remained awake all night reading Shakespeare's dramas, which next morning he was able to remember with surprising accuracy.

Dr. A. P. CAWADIAS mentioned the case of a young man who for years had felt rather tired and sleepy. He consulted three years ago a distinguished neurologist, who told him that his sleepiness was due to Raynaud's disease and put him on benzedrine. During the last two years he had taken 40 mg. of benzedrine every day, and showed very distinct symptoms of mental depression. But he declared that with 20 mg. he could not get on, whereas with 40 mg. he was able to do so. Was not that a form of addiction?

Dr. E. R. CULLINAN mentioned the case of a woman aged 60 with considerable coronary disease who had been taking 10 mg. twice a day for ten months. The longer she took it the greater was her depression when she left off taking it, but she did not require a larger dose to produce the effect at the end than she had done at the beginning. He also mentioned a child of 3½ years who had chewed a benzedrine inhaler left in the nursery and afterwards chattered incessantly for eighteen hours.

Dr. IVOR DAVIES, in replying on the discussion, said that he believed, though the substance had a wide use in psychiatric medicine, the only accredited indication for it

in general medicine was Parkinsonism. The dose in Parkinsonism was raised to as much as 20 mg., and it might be combined with the ordinary remedies.

CLEFT-LIP AND CLEFT-PALATE

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on October 14, with Mr. A. A. McCONNELL in the chair, the president, Mr. WILLIAM DOOLIN, delivered an address on congenital clefts of the lip and palate.

Mr. Doolin said the usual incidence of congenital defects of this kind would appear to be about one in rather less than 1,000 births; at this rate some fifty to sixty cases a year should be met with in the hospitals of Ireland. His own experience consisted of 196 cases seen in six years, 122 of which were clefts of the lip. The cases were grouped according to Veau's classification: simple unilateral (cleft of lip only without cleft of alveolus or palate), forty cases; total unilateral (cleft of lip, alveolus, and palate), sixty-eight cases; simple bilateral, two cases; total bilateral, twelve cases. In the case of the simple cleft-lip, the operator's task was to provide an effective closure of the interrupted oral sphincter within its muco-cutaneous envelope. Elaborate cosmetic efforts were not to be encouraged. In the total unilateral cleft the surgeon had a triple objective—closure of the nasal floor, closure of the lip defect, and reconstruction of the nostril. The bilateral cleft lip was best treated by a two-stage operation, each side being closed separately with an interval of three or four months between the two stages: the remaining cleft in the soft palate was best closed in the second half of the second year. There was a definite mortality attached to these operative procedures: in 107 operations for closure of unilateral clefts five deaths had occurred—two from post-operative hyperpyrexia, two from bronchopneumonia, and one from sepsis; in fifteen closures of bilateral clefts there had been one death, also from hyperpyrexia. This post-operative hyperpyrexia haunted all operative procedures on infants: its aetiology was unknown and its treatment purely empirical.

ENGLAND AND WALES

Obstetricians and Gynaecologists: College Dinner in London

The eighth dinner of the British College of Obstetricians and Gynaecologists was held at Claridge's on October 28, with the President, Sir Ewen Maclean, in the chair. Beside him were the President of the Royal College of Physicians of London (Dr. Robert Hutchison), the President of the Royal College of Surgeons of England (Mr. Hugh Lett), the President of the British Medical Association (Dr. Colin Lindsay), and the Secretary of the Ministry of Health (Sir George Chrystal). The guests, who included many ladies, were received by Sir Ewen Maclean and Miss Maclean. After the loyal toast had been honoured the health of "The College" was proposed by Dr. Robert Hutchison, who said that the early disapproval of the Royal College of Physicians at the birth of the College of Obstetricians and Gynaecologists had not perhaps been a disadvantage. The new College had flourished and justified its existence as a focus of information on all public matters relating to the twin subjects with which it was concerned. In his reply Sir Ewen Maclean spoke of the bonds of common interest between the Colleges,

old and new, and recalled how Dr. Herbert Spencer in his Harveian Oration had brought out Harvey's contribution to obstetrics. He himself was now at the end of three years' presidency, and his gratitude to the officials was as great as the gratitude he felt when quitting the presidency of the British Medical Association. Reviewing the present position of the College he noted that it now numbered 800 Fellows, Members, and diplomates, 231 of these living over-seas. In its efforts to raise the standard of midwifery practice throughout the British Empire it was consulted by great public bodies such as the Ministry of Health and the L.C.C. Sir Ewen Maclean ended with a tribute to the late Sir Robert Johnstone, a reference to Mr. Jeffcoate's Blair-Bell memorial lecture, of which a report appears this week at page 959, and a welcome to his successor in the presidential chair, Professor Fletcher Shaw, and to Professor Shaw's successor as honorary secretary, Mr. G. F. Gibberd. The toast of "The Guests" was proposed in a felicitous speech (which he called a "joint indictment") by Professor Daniel Dougall. Mr. Hugh Lett as first responder, in the absence of Lord Horder, made sympathetic reference to the history of the British College of Obstetricians and its fine ideal for improvement of the standard of midwifery. The Cinderella of ten years ago had now grown up; she had a home of her own and a lovely gown. The toast was also responded to by Mr. Norman Birkett, K.C., who, in an amusing speech, said that nowadays it was a rare experience for him to follow a "leader." Ending on a serious note Mr. Birkett declared that the co-operation of medicine and the law was of the greatest importance to the welfare of the State.

Congested Populations

On October 27 Dr. Norman Macfadyen delivered a Chadwick Public Lecture on "The Evils of Congestion and the Way Out." Dr. Macfadyen showed how great cities provided an unsuitable environment for families, and urged the creation of new towns as a means of opening up the big cities and thus providing better environments for the citizens of the too crowded townships. The slums were not merely collections of decrepit insanitary houses; they constituted places where the inefficient members of the population herded together, and poverty, ill-health, crime, vice, drunkenness, discontent, and mental feebleness congregated, producing a stifling atmosphere which tended to standardize undesirably the physical and mental lives of the young. Slums were to be found in every congested area, and rats, flies, bugs, and other unwholesome organisms flourished in them; they produced bad citizens as well as ill-health. Members of the "social problem" group in these areas tended to intermarry and to cluster together. This group cost the nation an enormous annual expenditure on the treatment of disease, both physical and mental, in respect of the police and of courts of law, and in the relief of misery. Its members were not restricted to congested areas, but where the standard of life was higher and the individual citizen had an opportunity of wholesome life there was a much greater chance of dealing with them satisfactorily. It was well known that the dispersal of such groups to better environments, where they could have their own houses and gardens and fresh air to breathe, produced an immediately favourable response in at least 80 per cent. of them. Dr. Macfadyen had found from his own experience that persons rescued from some of the most crowded boroughs in London and brought to Letchworth had changed into good citizens, the children had become healthy and more responsive and alert, influencing their own parents most favourably. Environment had both physical and intellectual aspects, including the nature of the domicile and its surroundings, the parents and the social life around them. The clearance of one small congested area in consequence of tuberculosis had been calculated to amount to a saving of £32,000 in three years. Dr. Macfadyen condemned blocks of flats because they increased the density of the

population on a given area, making the actual congestion worse. Even though, by a great expenditure of money on land, building, and public health services, the conditions of flat-dwellers might be ameliorated, they would not promote health. Flats were unsuitable for healthy family life; they seemed to have been designed for the storage of "hands" for industrial purposes. The congestion in great cities should also be blamed for most of the modern neurosis, which in its turn was responsible for one-third of the disease treated under national insurance. These neurotic conditions caused untold misery, suffering, social disability, and even physical diseases. In respect of the new towns advocated by Dr. Macfadyen, he added that each should be surrounded by an open belt of country, sufficient to demarcate it from other towns and to limit its own size. This open belt should provide the new town with playing fields, open spaces, and agricultural and dairy produce. If possible, the new town and its rural belt should be under a common ownership of the land. The town should be big enough to provide all the functions of an active social life, but it need not try to compete with the amenities of a great city.

Surgical Instrument Makers at Dinner

Surgical instrument makers and their guests met at dinner on October 28 under the chairmanship of Mr. Guy Radcliffe Drew. The health of the Surgical Instrument Manufacturers Association was proposed, in a speech full of historical lore, by Professor R. E. Kelly of Liverpool. He congratulated those engaged in this craft on the guild spirit which they were instilling into their younger members. As the son and brother of cutlers he himself from his earliest years was interested in the shaping of steel tools. Although an enormous number of surgical instruments had been invented, very many of them had enjoyed only a brief period of use, but the simplest instruments used to-day were extraordinarily old. Surgical operations were of great antiquity, none of them could have been done without tools, and the craft of the surgical instrument maker was probably the oldest in existence. At the Royal College of Surgeons there were skulls from Peru dating from the Stone Age showing holes laboriously made. The purpose of the drilling, no doubt, was not for the removal of cerebral tumour, but for the letting out of evil spirits or the letting in of good; the fact remained, however, that craniotomy was done in that early period. In the time of Hippocrates trephines, knives, bone drills, probes, needles, forceps, and bone elevators, among other instruments, were in existence. In the Naples museum, among the instruments which had been found in the doctors' houses of ancient Italy, were rectal speculae. Nor was bronze the only metal used in those days. Years before Hippocrates iron, and he believed steel, were made. A very strong and pure ore was used, and iron was produced by means of charcoal. Many of the "new" inventions, added Professor Kelly, were a good deal older than was supposed. Mr. Radcliffe Drew, in responding to the toast, mentioned that one of the problems of the surgical instrument maker was that he worked for the most part with alloys. It was true that he also worked with gold and a number of other pure metals, but not to any great extent. The properties of alloys were not fixed by their composition. If chromium were mixed with ferrite or carbon the end-result did not depend purely on the percentage of one material or the other, but very much on the temperature at which cooling took place. It was on account of the varying qualities possessed by alloys that the surgical instrument industry had become a rather difficult but also a fascinating business. The first problem was to train the workpeople to handle the material. At least five years was spent by the apprentice in learning to shape materials as required. The technical staffs in their workshops had not only to understand the laws of the material with which they were dealing, but also the exact conditions—environment, pressures, and so forth—under which the material was going to be used. It was on that account that contact between surgical instrument makers

and surgeons was necessary. The health of the guests and of the ladies was proposed by Mr. T. M. Proudfoot, and responses were made by Mr. H. S. Souttar and Mr. St. John Buxton. The former mentioned some amusing answers given by students at examinations for diplomas of the Royal College of Surgeons; some of them had a confused idea as to the uses of surgical instruments.

Silver Jubilee of Ruthin Castle

An interesting landmark in the history of clinics, nursing homes, and private hospitals in this country is reached with the celebration this autumn of the silver jubilee of Ruthin Castle in North Wales, the institution of which during the whole of the twenty-five years Sir Edmund I. Spriggs has been senior physician. Actually this clinic has been located at Ruthin only during the last fifteen years. It began its operations at Duff House, Banff, in 1913, when, it is claimed, it was the first institution of its kind in Great Britain. The hospital for private patients with nursing staff was already known, but Duff House had a whole-time salaried medical staff, with what would now be called registered auxiliaries for physical treatment, dietetics, radiography, and so forth, all under one roof. The original suggestion was for a sanatorium for gastric diseases, but the range of work was at once extended to include the scientific investigation and treatment of all diseases except infectious diseases, active pulmonary tuberculosis, and mental and severe nervous disorders. The work was carried on in Scotland for ten years, and then, in response to a desire to be nearer the centres of population, the move was made to Ruthin Castle, which was purchased, together with some five hundred acres of land. Ruthin Castle, overlooking the broad valley of the Clwyd, was one of the great fortresses erected by the first Edward as military bases in Wales. The ruins of the Plantagenet castle are still to be seen, with moat and dungeon complete, but they have been surrounded by another group of buildings of various ages. When the property came into the hands of those responsible for conducting the clinic the older buildings were made only the nucleus of the new hospital, and two new wings containing forty-six rooms for patients, as well as rooms for treatment and administration, were added. During the quarter of a century there have been 12,000 admissions. A special matter of pride to the highly qualified staff which has worked under Sir Edmund Spriggs's direction is the amount of research on various aspects of internal medicine which has been possible under these conditions for the study and treatment of disease; this is illustrated in about one hundred published papers.

Extension at Manor House Orthopaedic Hospital

A new wing, comprising three wards with sixty beds, was opened by Queen Mary at the Manor House Hospital, Golders Green, in North-West London, on October 24. Manor House is an orthopaedic hospital, owned and controlled by a quarter of a million industrial workers, each of whom is entitled to its services on a subscription of one penny a week. Mr. A. V. Alexander, formerly First Lord of the Admiralty, who is the president of the hospital, stated that the opening of the new wing coincided with the coming-of-age of the institution, which was started in 1917 to assist in the care of wounded soldiers. The present membership included shipwrights, engineers, printers, transport workers, and men engaged in every form of industry in all parts of the kingdom, but some of the most valued members of the hospital were employers of labour who had given valuable time and thought as well as money for the hospital's welfare. Mr. Alexander also said that, including the clinic for rheumatic patients and the special departments for dental and ophthalmic treatment, the hospital had raised since 1920 for maintenance purposes over £650,000, and nearly 100,000 patients had been treated, 19,000 of them in the wards. In order to complete the main hospital scheme for men it would be necessary to raise nearly £200,000, and it was also desired to extend the services to women. A house near by had

been already purchased for this purpose, and about £20,000 was in hand towards the erection of the first block of women's wards to cost not less than £40,000. Queen Mary declared the hospital open, and after making a tour of the new wing and of an occupied ward in the older part of the hospital, took tea in the quarters of Sir Ambrose Woodall, who has been resident surgeon at the hospital almost since its foundation.

SCOTLAND

Wilkie Research Surgical Laboratory

At the half-yearly meeting on September 28 of the General Council of Edinburgh University, Principal Sir Thomas Holland, who presided, said that as a memorial to the late Sir David Wilkie it had been decided to call the Department of Surgical Research, which was opened last July by the Minister of Health, the Wilkie Research Surgical Laboratory. At that time it had been intimated that the extension of the laboratory had been made possible by the help of a donation from an anonymous friend. He might now announce that the donor had been Sir David Wilkie himself. Parliamentary grants to Scottish universities for the present year, it was stated at the same meeting, amounted to £378,000, representing 41.8 per cent. of the total income, while the grants from local authorities amounted to 4.2 per cent.

Hospital Co-ordination in Edinburgh

Professor L. S. P. Davidson, in his inaugural address on taking up the duties of the chair of medicine at Edinburgh University, advocated a co-ordinated hospital policy. He pointed out that large numbers of beds in the municipal general hospitals were empty, while the Royal Infirmary had a waiting list of 3,000. One reason was that patients entering a municipal hospital had to pay part or all of the cost of maintenance if they were able to do so, while patients entering the Royal Infirmary paid nothing. He saw no objection to the principle that those who could afford to pay should do so, but the method adopted by the local authority of applying this principle was wrong. A hospital policy for the south-east of Scotland should be planned on a regional basis. This, however, presented many difficulties, and meanwhile it might be advisable to concentrate on the problem of a local hospital policy for Edinburgh with its half-million inhabitants. There were some twenty separate hospital governing bodies, but the problem might be simplified if the two main groups of hospitals, voluntary and municipal, were considered. The standard of teaching remained as high as it had ever been, but there was an excess of students undergoing clinical instruction. The local authorities might lighten the load of the voluntary hospitals; every vacant bed in the municipal hospitals might be made available for the care of the sick of Edinburgh who required institutional treatment. Much had been done to improve the municipal hospitals during the past six years, and he believed that the principle of patients contributing to their maintenance should be applied in the voluntary hospitals also. Admission to the municipal hospitals should be under the control of the medical officer of health, not the public assistance department, and the question of recovering the cost of maintenance should be investigated by professional almoners. It would appear, Professor Davidson continued, that a proper solution would be found in the formation of a contributory scheme open to all persons in Edinburgh with an income below a certain level. Subscribers to this would be admitted free to any hospital in the city, while non-subscribers would be questioned by the almoners to decide their ability to contribute to the cost of maintenance. Contributory schemes and organized almoner services had literally saved the voluntary hospitals in England, and the time was coming when the great Scottish institutions would have to follow suit.

Correspondence

Treatment of Poliomyelitis

SIR,—In your leading article on the above subject (October 22, p. 841) you stress as an important result of the investigation into Miss Kenny's work, although having no direct connexion with it, "the great value of collecting cases of poliomyelitis at an early stage of the disease into the wards of a hospital in which they can be subjected to intensive treatment by a team in which medical, surgical, nursing, and physiotherapeutic services are included." Anyone who visits orthopaedic clinics run in connexion with school medical and infant welfare services will hope that this comment may gain the fullest attention in the profession.

In spite of all the light that has been focused on this disease in recent years certain unfortunate tendencies are still apparent. In many hospitals, and not a few teaching hospitals, anterior poliomyelitis in its early stages is regarded as a "medical" condition, with the result that the patient is admitted to a medical ward under the care of persons unaccustomed to orthopaedic problems during the all-important early weeks of the disease. The heavy and largely inefficient plaster splint in which deformity has been allowed to occur (representing, not infrequently, a house-physician's first attempt at plaster work) is still no rarity.

Cases of anterior poliomyelitis—particularly the milder cases—are frequently discharged from hospital—perhaps with instructions to attend a massage department twice a week—very early in the convalescent stage after little or no hospital treatment and with no adequate arrangements for subsequent supervision. Many of these cases ultimately find their way to orthopaedic clinics or outpatient orthopaedic departments, but only too often after valuable weeks or months have been lost, and not infrequently after the patients have developed contractures that should never have been allowed to occur. If only it could become a universal practice for all cases of infantile paralysis to be referred to orthopaedic clinics or outpatient departments having facilities for prolonged hospital treatment for patients requiring it and an efficient follow-up system, not a little of the disabilities which are so often seen as a result of this disease could be prevented.

—I am, etc.,

Lord Mayor Treloar Hospital,
Alton, Oct. 26.

H. H. LANGSTON.

Civil Medical Organization in War

SIR,—The views expressed so clearly by Sir Frederick Menzies on civil medical organization in war (*Journal*, October 22, p. 860) must carry weight seeing that he has been a member of five committees which have come and gone and left little mark behind them. He points out the danger of collecting large numbers of valuable medical personnel under one roof, and although the risk is the same for all, the loss in the case of the medical personnel is much greater. This argument, however, applies anywhere where technical knowledge is gathered together, either in the staffs of armies or the organizing centres of large manufactories, and is one of the risks to be faced in war time. This risk, however, should be cut down to a minimum. The senior students are to be exempted from conscription so as to enable them to help in the hospital where their knowledge is most useful.

and pursue their clinical studies practically, becoming medical officers eventually.

The junior student's position was doubtful; but I hear that it is practically decided to exempt him also and allow him to pursue his studies, replace the senior student in the hospitals, and eventually, if war lasts long enough, to become a medical officer. But it will be useless to keep him in London, where he would certainly do no work even if any teaching was available. One hospital proposed using junior students as stretcher-bearers, but far less valuable material can be used, and exemption should mean that they seriously pursued their studies. A constantly bombed town is no place for them. They should be transferred at once to medical schools at a distance: Bristol, Cardiff, Liverpool, and the great medical centres of the North. Arrangements to do this should be made now. Perhaps each medical centre might agree to take all the students of one hospital, so that they could keep together and the deans could keep in touch with them. Whatever steps are deemed necessary should be taken *now*, and it is for the deans to move; no Government official is going to make suggestions to them.

What Sir Frederick Menzies states about ambulances and first-aid posts is equally true. The ambulance service was quite inadequate, and no stretchers were available. The ambulance service can be supplemented to start with by private cars, which can deal with sitting cases, the few ambulances being reserved for the lying-down cases. Most hospitals had collected the names of those willing to help with cars, and any hospitals which have not done so should do so at once. Many drivers were ladies. To be really prepared each driver should be asked to drive once or twice at night with lights dimmed and wearing a gas mask. They will not find this easy.

In organizing first-aid posts these should not be regarded as something apart from the hospital. They are all extremities of the hospital centre, and the most suitable place to have the largest and most important first-aid post is the hospital itself, to which the inhabitants are already in the habit of going for medical aid. What the hospital should avoid is the admission to its doors and corridors of the slightly wounded walking case who is brought in by a friend or neighbour, who must, of course, come in with him. They do more to get in the way and upset organization than anything I know. A school or large garage close to the hospital and joined by a covered way, even if it is only canvas, is the ideal, and the whole casualty department of the hospital should if possible be transferred to it, and the hospital buildings reserved for the more severely wounded cases. This is near enough to allow cases requiring further operation to be transferred to the hospital without an ambulance. So many organizations are making the mistake of setting up these centres just a little way from the hospital, under the impression they are helping. They actually double the work, as the hospital must have a casualty department. It can be largely run by the neighbouring practitioners, the St. John Ambulance, and Red Cross; the hospital staff attending to the more serious cases.—I am, etc.,

London, W.1, Oct. 31. DUNCAN C. L. FITZWILLIAMS.

Air Raid Precautions

SIR,—It would appear to me to be extremely unhealthy and wasteful if the plans for our safety in war time are completely divorced from the necessities of peace. In rehousing our people where tenements are necessary in large cities it can surely be arranged that the basement is half underground and therefore easily sand-bagged;

it could be used during the busy time of the day as a garage for cars and after school hours and during the week-end as a playground for children on wet days, with a warden in charge of the basement to issue to our somewhat unruly children bats and balls according to the games which are locally encouraged in such spaces. A small space under a large tenement could be so constructed that it could easily be converted into a first-aid post or decontamination centre in war time. It has been considered wise to issue gas masks in certain areas; we have yet to hear the price we must pay for the renewal of this life-saving apparatus.

In peace time we have an enormous number of road smashers, and injured people remain for quite a long time on the roadside until the ambulance arrives without first-aid dressings. Could not every motor-car be compelled to carry two "field" and two "shell" dressings as part of their essential equipment. These "field" and "shell" dressings should be so stitched that they can be opened out to cover twice the area, and should be identical with those issued to the troops in order that everyone is familiar with the size and use. The storage of such dressings would then become part and parcel of civil life, easily turned to advantage during war time, the present dressings in first-aid boxes in factories being useless for road accidents or air raid casualties.

We are inclined to scoff at the Government departments, but if an intelligent observer were posted at the entrance of a large hospital for one week he would be astonished at the various shapes and sizes of stretchers which bring in the sick from the ambulances supplied by the police, contributory schemes, corporations, and private firms. How can waste be avoided if in peace time stretchers do not conform to a standard pattern, duplicates of which should be stored in racks in the main casualty departments, so avoiding unnecessary delay while police, etc., wait for stretchers to be cleared, and again in war time affording a tremendous stock of available stretchers? Indeed, every hospital should be required to store a minimum of eight stretchers for every hundred beds. The training also of the various enthusiastic first-aid workers should be more closely linked with the hospitals. Most of these hospitals have rooms, models, etc., for the training of their nurses, which could be used and be better equipped by massing this type of social service, whether it be given by ambulance teams of dock workers, miners, V.A.D.s, A.R.P. personnel, Boy Scouts or Girl Guides—all valuable auxiliaries but requiring better co-ordination and a dash of experience which the hospitals alone can supply.—I am, etc.,

R. KENNON.

Liverpool, Oct. 24.

SIR,—May an outsider be allowed to comment upon the recent correspondence in your columns regarding the medical profession and air raid precautions. That the bomber will get through in large numbers, that congested populations are military objectives of the first order, and that the outbreak of war would mean, from the first, many thousands of casualties a day, these are facts admitted even by the most complacent of our politicians. Hospitals and hastily improvised accommodation crowded beyond capacity within a week; doctors and nurses working, themselves unprotected from the ceaseless relays of bombers, on intricate surgical cases—these are but the milder scenes we must anticipate. The Government, which has as yet evolved no proper plans for clearing stations, emergency accommodation, or structural protection for the great hospitals, is laying a most unfair burden upon the medical profession.

In my own comfortable profession, whose members have little responsibility beyond themselves, some apathy and complacency seems inevitable. But doctors should be the first to put forward a demand for a vigorous and extensive policy of protection. More readily than politicians or civil servants, who talk so airily of "half a million casualties in the first week," doctors realize that prevention is better and easier than cure. Air raid shelters are the solution. As a professional historian and a realist I pin my faith, like Hitler, to steel and concrete and paid labour, rather than to our present fantastic blend of gas-drill and voluntary principles. If members of the medical profession joined my college history classes and noticed how every British Government to date has fought its wars in the light of the *last* war, they would be doubly disturbed to see the old story now repeating itself.

I envisage a strict non-party propaganda organization for air raid shelters. It would principally consist of professional men, who possess the grasp of principles, the technical knowledge, the foresight, the freedom from political and commercial ties in sufficient measure to form the spearhead of the attack. If any members of your profession are interested in the idea I should be glad to hear from them.—I am, etc.,

Prognosis of Anxiety States

SIR,—The comments in your correspondence columns on my paper on prognosis of anxiety states call for some reply. Dr. R. Macdonald Ladell (October 8, p. 763) stresses "the willingness of the patient to contribute to life" as the chief prognostic point. The absence of this is surely what I have referred to as psychopathic personality, allotting it great importance, especially in persistently Grade I cases. On the other hand, many chronic neurotics are capable of constructive work, so that its significance should not be overestimated. I endorse his remarks concerning the difficulty of determining the goodness or badness of the environment without a profound knowledge of the patient's circumstances, and readily admit that I did not possess this knowledge, but it would have been of interest if the presence or absence of gross social evils had shown some consistent effect.

Dr. F. Dillon (October 15, p. 812) reproaches me for having made no attempt to assess the value of treatment. This is a matter of the greatest difficulty, which is enhanced by the chaotic way in which the end-results of treatment are published, and I make no apologies for failing to tackle it. I could not determine accurately how much and what type of treatment each case had received, especially since many had attended other clinics also. Only three had had prolonged analytical treatment: one, a full Freudian analysis; two, shorter ones of about six months' duration. All three persisted in their original grades. It was noticeable that many of the completely recovered cases had only made one or two visits to the out-patient department, and so had evidently received very little treatment. It is therefore obvious that spontaneous recovery may occur.

I must apologize to Dr. T. A. Ross (October 1, p. 721) for having misrepresented the duration of his follow-up, and must thank Dr. A. M. B. Walker (October 29, p. 922) for having drawn attention to a very interesting paper.—I am, etc.,

London, W.1, Oct. 31.

ARTHUR HARRIS.

Catarrhal Jaundice

SIR,—In the *Journal* of August 27 (p. 437) Dr. C. E. Lakin surveys the different forms of jaundice. He describes the two possible types of catarrhal jaundice: (1) catarrhal jaundice proper; caused by a blocking of the common bile duct secondary to an acute gastro-duodenitis; and (2) a subacute liver necrosis. He lays stress on the difficulty in distinguishing between these two forms, and he is right, I think, in being doubtful about the help given by the pre-icteric history. May I be allowed to refer to the Takata-Jezler reaction in the serum: the modification I have described (*C. r. Soc. Biol.*, Paris, 1935, 48, 534; *Guy's Hosp. Rep.*, 1936, 86, 166) seems to help in the differential diagnosis of the two forms. I have found that this simple reaction, which consists in a precipitation of the globulin fraction of the serum by a complex mercury salt (formed by mixing sublimate of mercury with sodium carbonate), gives a massive precipitation with the sera of patients suffering from parenchymatous liver disturbances, but is negative, or only slightly positive, in cases of catarrhal (obstructive) jaundice. G. Cozzutti (*Diagn. e Tecnic. di Labor.*, 1936, 7, No. 15) has had similar results. The number of my own cases (fifteen) is too small to allow of a final conclusion being drawn, but I think it would be worth while for someone who has the facilities to study the results of this test on a larger number of suitable patients.—I am, etc.,

London, W.1, Oct. 28.

H. Ucko.

Adrenaline Treatment of Asthma

SIR,—Dr. Joah Bates raises an important question in his letter (*Journal*, October 29, p. 921) on the adrenaline treatment of asthma. He points out that the employment of adrenaline during a cold in the head is not seldom followed by a very rapid spread of the infection to the lower bronchial tract. This, I believe, only occurs if the adrenaline is applied locally. I have drawn attention to the fact (*Journal*, March 21, 1936, p. 609) that the local application of any remedy containing adrenaline or ephedrine to the nasal mucous membrane, although it produces a very pleasing immediate effect due to the vasoconstriction of the mucous membrane, does ultimate harm because the vasoconstriction is followed by a reaction, when the turgescence becomes greater than ever; and the more frequently the vasoconstrictor effect is produced the more marked is the resulting vasodilatation. This is more striking when a spray containing adrenaline or ephedrine is used for the relief of asthma. The immediate effect is delightful, but the ultimate result from the reactionary vasodilatation of the bronchial area in most cases is disastrous. So bad may the dyspnoea become that neither the injection of a large dose of adrenaline nor any other remedy will afford relief.

I believe that I was the first in England to give adrenaline by injection for asthma, and in the many years since then I have not met with a case in which addiction to adrenaline has resulted when given by injection. Repeated hypodermic injections of adrenaline produce no pleasurable effect beyond the relief of the dyspnoea, and after a time they make the skin so hypersensitive that patients are only too glad to make use of another remedy to avoid the pain of an injection. I had one asthmatic patient who, as the result of repeated operations for the removal of nasal polypi, had required over 60,000 injections of adrenaline, and the only adverse effects these had

upon him were that his skin became so tough and hypersensitive that he needed a specially sharpened hypodermic needle, and his blood pressure became abnormally low. He never needed to increase the dose above 5 minims.—I am, etc.,

London, W.1, Oct. 29.

ALEXANDER FRANCIS.

Idiopathic Epilepsy

SIR,—I was much interested in Dr. Robert G. Linton's remarks on idiopathic epilepsy (*Journal*, October 22, p. 837). I have no definite theory, but my own observations have led me to rely on two remedies that I do not know to have been used by others. I have found that apomorphine injected hypodermically in amounts sufficient to cause vomiting invariably stops fits immediately, sometimes even before the needle has been withdrawn. For the prevention of fits I have found hyoscine usually effective in doses of 1/100 grain by the mouth every night. I believe many cases of nocturnal incontinence of urine are due to epilepsy, though not diagnosed as such, and hyoscine is very effective in these cases also.—I am, etc.,

Bristol, Oct. 24.

E. BLAKE GARLAND.

Ether Convulsions

SIR,—In the correspondence about late ether convulsions which has appeared in the *Journal* of October 22 none of your correspondents mentions too deep an ether anaesthesia as a cause of this condition.

We know that an excess of carbon dioxide can cause twitchings which are indistinguishable from the onset of late ether convulsions, and Dr. C. L. G. Pratt's letter (p. 864) leads us into a maze of biochemistry to show how this is brought about; yet these convulsive states are hardly ever reported when ether has not been the principal anaesthetic agent. In my own cases the pupil was always widely dilated when convulsions first started, and in each case I was trying to get the utmost relaxation possible in order to facilitate the surgeon's work. Had I added some chloroform to get this extra relaxation I feel that convulsions would not have occurred. I have had no further cases since adopting this rule.

Convulsions are so often reported in patients who are toxic that sepsis has now come to be regarded as a factor which, combined with ether, will favour the onset of convulsions, but it must not be forgotten that an ill patient requires very much less anaesthetic to produce a given depth of anaesthesia than a non-toxic patient, and I venture to predict that when the signs of anaesthesia are properly taught in our medical schools late ether convulsions will very rarely be reported.—I am, etc.,

London, W.1, Oct. 24.

J. U. HUMAN.

Modern Decline of Breast-feeding

SIR,—At the risk of pursuing the correspondence on Dr. J. C. Spence's article on the decline of breast-feeding, I feel that Dr. J. Simon's observations on child welfare centres must not be allowed to pass unchallenged. I have worked both in country districts and in a large metropolitan borough, and I happen to be vice-president of the Women's Public Health Officers' Association, which brings me in contact not only with my own health visitors but with women from all parts of the country, and it seems unbelievable that any doctor of standing

can hold the views put forward by Dr. Simon. In my experience it is the efforts made at the clinics by teaching and demonstrating breast massage and complete emptying of the breasts which very often re-establish lactation. There are few general practitioners who have the time or the inclination to visit daily the homes of working-class mothers, who are struggling unsuccessfully to feed their infants naturally and from whom fees are seldom forthcoming. Surely child welfare centres working in co-operation with the general practitioners can *only* do good work.—I am, etc.,

Basingstoke, Oct. 8.

HILDA M. PRICE HUNT.

SIR,—Many must have felt like myself that Dr. J. C. Spence's article about breast-feeding was much needed. Of course we all believe in breast-feeding, but how often can we secure it? Most writers reiterate what we already know—that it is desirable, etc. Dr. Spence seeks to tell us why modern women cannot support the offspring she has contrived, often despite herself, to manufacture.

There have been times when I have felt that there is a definite physiological lack in modern women. But it cannot be so. Surely such a far-reaching change could not arise in one generation! No, it must be either (1) the desire *not* to lactate, or (2) the effect of recent factors in environment. I believe both are in operation. How often am I told that bottle-feeding is less trouble (and with the pseudo-educated labouring classes where *any* milk in *any* bottle suffices I believe this may be true—if the child can stand it), or even that breast-feeding is a dirty business! With such women I achieve nothing. But there is also the question, as Dr. Spence says, of wrong atmosphere and wrong advice. And I believe that the nurse must usually be blamed for this. One cannot learn such things from books and lectures. I don't believe a woman can be a good (as opposed to a competent) midwife unless she has had a child of her own.

The modern mother and her baby are not allowed to know each other. They are kept apart, lactation is emotionally discouraged by giving bedpans, etc., before feeding, the baby is expected to have a time clock for a stomach, and must on no account have any human sympathy. Part of this regime is based on a jealous proprietorship. Doesn't every nurse refer to *her* babies? Despite their appalling ignorance of physiology and even of cleanliness, the old "gamps" may possibly have had some abilities the modern nurse does not possess. They at least had had children.—I am, etc.,

October 9.

JUVENIS.

Gold Treatment of Rheumatoid Arthritis

SIR,—It was with great interest that I read a letter from Dr. Maurice Newman (*Journal*, August 13, p. 375) regarding gold therapy. I entirely agree with Dr. Newman's report as to both the benefit derived from chrysotherapy and the disappointing results of vaccine in the case of rheumatoid arthritis.

For the past six years I have studied and used chrysotherapy in a series of some four hundred cases, having obtained the first batch of injections from France. In the majority of cases I alternated the injections with one of anahaemin, and the results have been more than satisfactory; in fact, some cases have benefited to a remarkable extent, bedridden patients having again become active members of the community. In not one instance have complications such as gold abscesses, albuminuria, or altered blood conditions arisen, and in some patients who showed a slight skin reaction the benefit derived proved

greater than in those not showing any reaction. I am now using vitamin C in conjunction with the gold injections, and this has proved very beneficial. In those cases showing a low blood count and haemoglobin, parenteral liver injections, I find, will prevent any risk of an agranulocytic state.

As regards vaccines, I did a good deal of work in this direction, but would not continue their use as the results were very disappointing and in no cases did the patients derive benefit.—I am, etc.,

SIDNEY ROSEBERY,
M.D., F.R.C.P.Ed.

Sydney, Australia, Sept. 21.

The Occipito-posterior Case

SIR,—Dr. B. E. Meek (*Journal*, October 29, p. 919) must be thanked for insisting that the proper use of obstetric forceps should be taught. They are the only means of producing the power necessary to deliver weakly mothers of children the average weight of which is definitely rising. Within the pelvis the axis of an impacted head with its oedematous scalp cannot be accurately determined by digital examination. The whole hand must go into the vagina. In the old days I always did this. But now, with an instrument that can harmlessly rotate the foetal head, I find I can omit the "whole hand" exploration in the majority of cases and extract after finding the position of the occiput; only if I cannot quickly find it does the whole hand go in. With regard to my second cardinal error, no cervix can fully dilate in a reasonable time below an impacted unadvancing head. So long as it easily admits the blades, can anything but good result from imitating by gentle rhythmic tractions (at three-minute intervals) the absent pains, with a finger-tip upon the stretching rim to estimate the power one may use? I believe that the future obstetrician will find this a cardinal procedure.—I am, etc.,

Somerset, Oct. 30.

DAVID PRICE.

"Science in Advertising"

SIR,—The annotation headed "Science in Advertising" in your issue of October 22 (p. 842) ends thus: "Medical men must view with some alarm the possibility of the profession thus being used in an advertising campaign." Possibility? Surely it is much more than that. The whole country must by now be familiar with drawings of medical men wisely diagnosing the patient's complaint from a wife's anxious description and prescribing the advertiser's product. From ordinary weekly and daily newspapers one can give the following list of goods advertised with "medical" catchwords, diagrams, or semi-scientific statements:

- 8 *Beverages*.—"Graph showing course of energy consumption during sleep."
- 6 *Breakfast Foods*.—"Calorie value tested "by a leading dietetic laboratory."
- 2 *Footwear Products*.—"Doctors say walking on [X] rubber heels saves jarring the spine and prevents headaches."
- 1 *Mattress*.—"Gives vitality because it keeps the spine straight during sleep."
- 1 *Linoleum*.—"Whose springiness is "the secret of inexhaustible vitality."
- 2 *Biscuits*.—"To avoid "excess of starch whose assimilation places undue strain on the whole constitution."
- 3 *Soaps*.—"Dirty hands may carry 27 Germ Diseases say Doctors."

Various Foods.—Wine (to restore nerve fibres); raisins (for iron); cheese (calcium, phosphorus, and milk minerals); jams (to balance the meal: "Appetite fact . . . dieticians say so"); salmon (proteins); and others.

2 *Beauty Products*.—"Three years of research by leading biologists" on a skin vitamin. ". . . A doctor told me X was the discovery of a great Vienna University Professor."

There are many others. Perhaps the nicest was the physician shown advising the housewife to use a certain soap at the kitchen sink since it washed away the fats which bred disease germs. The examples, it will be noted, are mainly household articles and not pharmaceutical products. It seems as if medicine has become the grocer's privilege.

The public must apparently be impressed by vague graphs, anatomical sketches, and rapid references to carbohydrates and vitamins. As a student I wonder if the general practitioner already has patients coming to him complaining of "fagged feeling," "night starvation," "starch heaviness," "cosmetic skin," and other recently created conditions. Such advertising tends to falsify the public's idea of medicine and leads to self-diagnosis. It increases the amount of unnecessary fear over ill-health which already exists. Natural foods must in many cases be discarded for the dearer branded goods.

A good example of the fear technique is a recently advertised beverage: "Heavens! What a sight I look! Is it nerves or lack of sleep?" Below this caption and its appropriate picture is an explanation that the product has been "discovered by an eminent doctor" to restore the body's mineral balance. A classified list of six minerals and eighteen diseases stated to be caused by their deficiency is appended. These vary from eczema to heart disorders.

Apart from general public education on the true aspects of nutrition and health, can anything be done against such advertisements?—I am, etc.,

A. S. PLAYFAIR.

St. Bartholomew's Hospital, E.C.1, Oct. 23.

Universities and Colleges

UNIVERSITY OF OXFORD

The examiners have recommended that the Rolleston memorial prize for 1938 be divided equally between N. V. Polunin, D.Phil., New College, and H. M. Sinclair, B.Sc., B.M., Fellow of Magdalen College.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—P. Baker, H. S. A. Corfield, S. K. Das, E. M. F. Decottignies, H. L. Francis, E. K. Gardner, J. M. Hardy, E. S. Nicholson, F. J. C. Smith, M. K. Twist, M. Whitehead.

MEDICINE.—H. S. A. Corfield, D. L. P. De Courcy, P. A. Dixon, J. R. F. E. Jenkins, F. P. S. Malone-Barrett, R. Rowlandson, V. N. Stevenage, M. K. Twist.

FORENSIC MEDICINE.—H. S. A. Corfield, D. L. P. De Courcy, P. A. Dixon, J. R. F. E. Jenkins, F. P. S. Malone-Barrett, R. Rowlandson, V. N. Stevenage, M. K. Twist.

MIDWIFERY.—E. J. S. Barthorpe, W. H. Clarke, P. H. Davies, D. L. P. De Courcy, D. S. G. Genge, K. R. P. Kent, D. B. Roberts, S. A. Schuyler, M. K. Twist.

The diploma of the Society has been granted to P. Baker, H. S. A. Corfield, P. H. Davies, P. A. Dixon, E. K. Gardner, D. S. G. Genge, J. M. Hardy, F. P. S. Malone-Barrett, F. J. C. Smith, and M. K. Twist.

Obituary

SIR R. J. JOHNSTONE, B.A., M.B., F.R.C.S.,
F.C.O.G., M.P. Northern Ireland

It is with sincerest regret that we record the death at his residence in Newcastle, Co. Down, of Sir Robert Johnstone after a short but trying illness. It seems but a few weeks since his attractive personality presided over the Annual Meeting of the British Medical Association in Belfast in 1937. The charm of his presence on that memorable occasion made for him many new and lasting friendships. Last year he retired from practice to his recently built home in Newcastle, and he was looking forward to following interests in other fields which lay open to his genius, his ability, and his experience.

Robert James Johnstone was born in 1872, a native of Greenisland, Co. Antrim, where his ancestors had been established for many generations. He was a student of the Royal Belfast Academical Institution, and from there entered Queen's College, Belfast, electing to pursue a medical course. In the College his career was distinguished, and eventually he adorned one of the most important chairs of the University, was a member of its Senate and many of its committees, and represented it with ability and eminence in Parliament and on the General Medical Council. In July last the Senate of the University decided to confer on him the degree of LL.D. (honoris causa), but owing to his illness this ceremony did not take place.

At Queen's College he had a brilliant career in the Faculty of Arts, his awards and scholarship being outstanding. In the Faculty of Medicine his progress was again marked by scholarships and exhibitions, leading to his qualification M.B., B.Ch. in the Royal University of Ireland in 1896 with honours. His postgraduate study was thorough. He acted as house-surgeon in the Royal Hospital, Belfast, for a year, and during the next six years was in succession demonstrator of anatomy, and of pathology under Professor Lorrain Smith, completing his studies in London and Vienna. Surgery attracted him, especially gynaecology. He had anatomy at his fingertips, pathology was the background of his knowledge, and a sound judgment coupled with skilful hands com-

pleted his equipment for a successful career. In 1900 he obtained his Fellowship of the Royal College of Surgeons of England, and became assistant to the late Sir John Byers, two years later joining the staff of the Royal Victoria Hospital as assistant gynaecologist. At this time, too, he was appointed to the Belfast Maternity Hospital. Robert Johnstone's progress in his chosen field was rapid. The increase in private practice and advancement in hospital appointments were an index of his proficiency and appreciation of his merits. With patients he was the soul of kindness without being sentimental; their welfare was ever his main concern, to the exclusion of his own interests or convenience. All over Ulster to this day there are grateful recollections of his skill, his sym-

pathy, and his humanity. He was a natural surgeon: deft with his hands; sound in his knowledge of surgery, pathology, and anatomy; perfect in his technique, and critical in his judgment. Not many surgeons could perform major operations with so few instruments, so little ritual, and so little shock to the patient. These qualities marked him out for progressive advancement, which increased the value of his services to the hospitals. In the Royal Victoria Hospital he became senior gynaecologist in 1919, and in the Belfast (later the Royal) Maternity Hospital he manifested a special interest, eventually becoming chairman of its committee of management. The development of the Royal Maternity Hospital from its original situation in Townsend Street was very near his heart, and its welfare one of his main interests; to it he devoted his talents and attracted the best of

everything to its service. It is typical of him that one of his last wishes was that anyone intending to send flowers to his funeral should, instead, send a subscription to this hospital. To the Royal Victoria Hospital he gave his professional services as gynaecologist freely and fully, and to its administration he contributed his sound advice and counsel. On the death of Sir John Byers in 1920 Robert Johnstone became professor of gynaecology in the University, and was ever an attractive and interesting lecturer to his students, with all of whom he was singularly popular and respected.

He was a member of the British Medical Association since 1897, being secretary of the Ulster Branch for seven years, president of the Branch in 1921, and eventually attained the highest honour of his career by being President of the Association in 1937. At the 1909 Annual

The October issue of the *Annales de Médecine* is devoted to septicaemia due to various organisms (*B. fundibuliformes*, *B. fragilis*, *Streptobacillus moniliformes*, *Streptococcus haemolyticus*, *B. coli*, and *C. diphtheriae*).

The King has approved the reappointment of Dr. Adam Rankine, M.C., to be a Nominated Official Member and Dr. Arthur Hutton McShine, O.B.E., to be a Nominated Unofficial Member of the Legislative Council of the Colony of Trinidad and Tobago.

The King has appointed Dr. James White Thomson (Senior Medical Officer) to be a Member of the Executive Council of the Presidency of Saint Christopher and Nevis.

The King has granted authority for Dr. George Herbert Garlick (Principal Medical Officer, Johore) to wear the Order of the Crown of Johore, insignia of the Second Class, conferred upon him by the Sultan of Johore in recognition of valuable services rendered.

Dame Joanna Margaret Cruickshank has recently been appointed Matron-in-Chief of the British Red Cross Society in place of the late Mrs. Rome.

The international Chauvin prize for oto-neurophthalmology has been awarded to Drs. Alfandary of Belgrade, Arslan of Padua, and Chardonnel of Nantes. The subject of the prize was a plan for the study of vestibular disharmony.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

The progressive rise in the incidence of acute poliomyelitis noted in the last three weeks is continued in the week under review; in the present instance the rise is entirely due to the increase in the cases in London. Of the 81 (77) cases notified in England and Wales 7 (11) occurred in Essex, 6 each in Nottingham (0), Glamorgan (2), Oxfordshire (12); and 4 each in Carmarthen (4), Sussex (6), and the West Riding of Yorkshire (2). More than one case was reported from the following centres: London 11 (4)—Camberwell, Lewisham, and Wandsworth 2 each; Battersea, Hammersmith, Holborn, Islington, and Poplar 1 each—4 each in Harwich (7), Eastwood (0), Oxford (11), Bristol (2); 3 in Penarth (0); 2 each in Tendring (3), Sedgley (0), Horsham (0), Birmingham (1), Sheffield (1), Carmarthen (0), and Swansea (0). The wide distribution and sporadic character of the disease are illustrated by experience in Mid-Sussex, where there were 19 cases with 2 deaths in the last three months, compared with 5 cases for the whole of 1937. The cases occurred largely in isolated dwellings, chiefly farmhouses, in the rural areas. An unusual feature in this outbreak is the age of the incidence of the disease, the majority of the cases being between 10 and 16 years, which is considerably above the age limit.

In Germany during the week ended October 8, 353 (337) cases were reported, chiefly in Bavaria 67 (54), Württemberg 60 (54), Baden 16 (12). In Rhenish Prussia the incidence of the disease decreased. In Denmark during the month of September 92 cases were reported, compared with 61 in the previous month. During the week ended October 15, 33 cases were reported in Holland, including 10 in the province of South Holland and 9 in the province of North Holland.

Enteric Fever

There was a slight increase in the incidence of enteric fever in England and Wales—37 (32)—in which London shared—12 (11). The counties from which more than one case was reported are: Middlesex 3 (Heston and Isleworth, Ruiship-Northwood, Sunbury-on-Thames), Durham 2 (Sunderland and Boldon), Kent 2 (Canterbury and Folkestone), Lancashire 2 (Eccles and Farnworth), Surrey 2 (Barnes and Esher), Sussex 2 (Uckfield and Horsham). The 12 cases in London occurred in Chelsea, Fulham, Kensington, and Wandsworth 2 each, Greenwich, St. Marylebone, St. Pancras, West-

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

minster. At the time of going to press an outbreak of typhoid fever involving 5 children has been reported at Wellow, near Eastleigh, Hampshire. The schools at Wellow (population 1,700) have been closed for a period of three weeks.

Primary and Influenzal Pneumonia

There was a further increase in the notifications of primary and influenzal pneumonia in England and Wales—534 (493)—and in London—45 (38)—during the week under review. The counties with the greatest increases are: Lancashire 105 (92), Leicester 11 (4), Norfolk 12 (5), Stafford 37 (24), Warwickshire 48 (38), Glamorgan 17 (9). The number of deaths in the 126 Great Towns rose from 12 to 26; more than one death occurred in Manchester 3 (1), Leeds 2 (0), and Liverpool 2 (0).

Diphtheria and Scarlet Fever

The rise in the notifications of diphtheria in England and Wales and in London referred to last week was continued during the week under review—1,367 (1,288) and 173 (138) respectively. The centres chiefly affected were: Derby 17 (9), West Ham 13 (3), Bristol 20 (8), Leicester 23 (17), Bethnal Green 19 (5), Camberwell 15 (9), Lambeth 14 (9), Lewisham 13 (7), Hendon 13 (3), Smethwick 16 (0), Croydon 18 (12), Leeds 31 (28). In Scotland, also, an increase was recorded, notably in Aberdeen 18 (13), Glasgow 78 (72), Edinburgh 14 (12), Fife County 12 (6), Stirling County 7 (3). Of the 17 deaths in the 126 Great Towns of England and Wales more than one occurred only at Croydon, 2 (0). There were 4 deaths from diphtheria in the 16 principal towns of Scotland during the week—2 (2) in Glasgow and 1 each in Aberdeen (0) and Paisley (1).

Notifications of scarlet fever in England and Wales and in London dropped during the week under review—1,864 (1,940) and 159 (186) respectively—and were well below the median values for the last nine years. There were 4 deaths in the 126 Great Towns: in Worcester 2, and 1 each in Oxford and Dewsbury. In Scotland the notifications rose from 355 to 395; the centres chiefly affected were: Glasgow 88 (71), Dundee 32 (21), Fife County 38 (32), Greenock 19 (13), Aberdeen 12 (10). There were no deaths from scarlet fever in the 16 principal towns of Scotland during the week.

Measles and Whooping-cough

There were only 2 deaths from measles (both in Merthyr Tydfil) in the 126 Great Towns of England and Wales during the week under review. Of the 26 (26) cases of measles notified in the administrative county of London the chief were in Finsbury 5; Deptford and Poplar 3 each; Lambeth, Shore-ditch, Stepney, and Woolwich 2 each. In Scotland 18 cases of measles were notified during the week, compared with 8 in the previous week; the centres chiefly affected were Glasgow 9 (3) and Orkney County 4 (0). Of the 4 deaths from whooping-cough recorded in the 126 Great Towns of England and Wales during the week 1 each occurred in Birmingham (1), Leicester (0), Kingston-upon-Hull (0), London (0). In London 131 (70) cases of whooping-cough were notified, distributed mainly as follows: Hackney 21, Southwark and Wandsworth 14 each, Lambeth 10, Stepney 9. In Scotland the notifications rose from 91 to 163 during the week, chiefly in: Glasgow 134 (66), Lanark County 12 (4). There were 4 (0) deaths (all in Glasgow).

Cholera: Plague

During the week under review there were 862 (1,455) cases of cholera and 433 (702) deaths in the Central Provinces of India, 330 (381) cases and 141 (161) deaths in Bombay Presidency, 223 (361) cases and 104 (161) deaths in the United Provinces. In China during the same week 87 (82) cases and 30 (24) deaths were reported in Shanghai and 7 (16) cases and 9 (7) deaths in Hong Kong.

In India during the week there were 73 (144) cases of plague and 5 (18) deaths in the Central Provinces, 88 (33) cases and 73 (26) deaths in Burma, 25 (30) cases and 11 (12) deaths in Madras Presidency, and 13 (13) cases and 8 (4) deaths in Bombay Presidency.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 22, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES ARE

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúir na h-Eiceann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin.)

QUERIES AND ANSWERS

Varicose Veins in a Haemophilic

Dr. H. E. CARMALT (Birmingham) writes: A haemophilic patient of mine has varicose veins and is rather anxious lest one of them should rupture. I did not advise injection of a sclerosing fluid as I think the usual clotting within the vein would not take place and there would be a troublesome haemorrhage from the site of puncture. I would be grateful for any authoritative opinion.

Ménière's Disease and Fruit Diet

Dr. V. E. HASTINGS writes from Auckland, New Zealand: Dr. James Adam says in his letter (*Journal*, April 16, p. 870): "The last two cases of Ménière's disease that I saw promptly got well on taking abundant fruit." This is in agreement with my own experience of two cases of Ménière's disease. These two patients were given diets which contained in one case a pound of fruit daily and in the other two pounds daily. Both had one and a half to two pints of milk, four ounces of raw greens, with the rest of the diet made up of potatoes, vegetables, meat, wholemeal bread, and butter. They both made rapid recoveries, in one case all giddiness disappearing in from two to three days, and in neither case has there been a return of symptoms after two and three years respectively. It would be interesting to hear what results others get from this treatment.

LETTERS, NOTES, ETC.

Sterilization of Syringes

Dr. TREVOR H. KNIGHTS (Belgian Congo) writes: I would like to add a word of support for the water-alcohol-ether sequence for the sterilization of syringes advocated by several correspondents. I used this method for three years as an assistant in a bacteriological laboratory. Syringes were sterilized in this way before drawing off blood for culture, the blood being immediately squirted into a flask of 2 per cent glucose broth at the bedside. I have no definite figures, but in over 200 such procedures I can only remember two plates showing contamination after prolonged incubation. In these blood cultures haemolytic streptococci, *Str. viridans*, and often pneumococci, grew strongly and were uncontaminated—a convincing proof. I always felt, of the efficacy of the method. I have, of course, heard the method strongly criticized on theoretical grounds—the short time-interval, the inadequacy of absolute alcohol in any case, etc.—but until more elaborate methods can give as reliable results I shall continue to employ this one. Our technique was simple. Immediately on returning from the ward the person

responsible washed the syringe thoroughly with water; tap water will do and does not need to be boiled, but all the protein matter must be removed. Any stickiness was dealt with by peroxide, or failing that 1 per cent. sodium bicarbonate, although the alkaline solution is to be avoided if possible. Then the syringe was rinsed with absolute alcohol, and finally ether, and left—the plunger separated from the barrel—on the top shelf of a bacteriological incubator or any warm, dry, dustless cupboard. When it was required for use the plunger was fitted into the barrel, and the syringe was rinsed first with absolute alcohol and then with ether. We sterilized the needles by placing them in a test-tube plugged with cotton-wool and containing 2 or 3 c.cm. of alcohol. The spirit was boiled off on a water-bath or more rapidly by heating the tube over the naked flame of a bunsen burner or spirit lamp. This gave a sterile, dry needle; there was no danger if the vapour issuing from the tube was ignited. In practice the alcohol-ether rinsing would do equally well for the needles. Also of value is the method I learnt for "unsticking" syringes by placing them on a block of ice for ten to fifteen minutes. I have never known this to fail, but it need never be necessary if the first careful washing with water is properly performed as soon as possible after the syringe has been used.

Dr. J. WALKER TOMB writes: In his letter to the *Journal* of August 6 (p. 317) Dr. E. W. Hayward asks for suggestions regarding a feasible method of sterilizing hypodermic syringes where repeated boiling is impracticable. If Dr. Hayward will refer to the *Indian Medical Gazette* of January 1, 1925, he will find such a method described by me under the heading "A Useful Hypodermic Outfit." The essential part of the method is that the syringe, having been sterilized originally by boiling, is thereafter maintained in a sterile condition by washing it out after each injection with a mixture of equal parts of rectified spirit and glycerin of carbolic acid. The rectified spirit evaporates quickly, more especially in the Tropics, leaving a very fine film of glycerin of carbolic acid behind, which not only keeps the interior of the barrel perfectly sterile, but effectively prevents the piston from sticking in the barrel. The needle described in the article is a platino-iridium one, and is sterilized in the first instance by boiling, and by flaming before and after subsequent use, but any modern high-grade stainless steel needle can be sterilized by flaming for a considerable number of times before losing its edge. Hundreds of injections have been given over many years with a syringe sterilized in this way without a single untoward reaction. The syringe has also been tested periodically in the laboratory for sterility and always found sterile.

Gas and Air Analgesia

The National Birthday Trust Fund for Extension of Midwifery Services announces an offer to all district nursing associations employing nurses who have qualified to give analgesia by the gas and air method of an approved machine at the greatly-reduced price of £5. This low cost will make it possible for all associations to obtain one. Applications should be addressed to the Secretary, National Birthday Trust Fund, 57, Lower Belgrave Street, S.W.1. Gas cylinders to fit the machine are supplied by a well-known firm, which undertakes to deliver and collect the cylinders at any address for 3s. 2d. per cylinder. Unused ones are credited, and the average cost of gas per case has been found to work out at about 4s. 6d.

Disclaimer

Dr. WILLIAM BROWN (London, W.1) writes: My attention has been drawn to a recent article in a Sunday paper in which a photograph of myself appears, and also the description of a case as being treated by me which was not a case of mine but a case of the late Dr. Georg Groddeck of Baden-Baden which I had briefly described in my last book. The article was written and published without my knowledge or consent, and the writer of the article is personally unknown to me. The photograph was one of myself ten years ago, and I do not know how it was obtained for the newspaper.

Corrigendum

In our report of the discussion on "Marine Therapeutics" (October 29), Dr. S. Watson Smith was misquoted at one point. The first sentence of the third paragraph on page 946 should read: "The southern region was to be recommended all the year round in the neuroses, insomnia, thyrotoxicosis, high blood pressure, granular kidney, and chronic respiratory disease, excluding tuberculosis."

- *Is there such a Condition as "Lipoid Nephrosis"? F. Rathery and P. Froment.—p. 1249.

Lipoid Nephrosis.—The authors discuss the question of the existence of "lipoid nephrosis" as described first by F. Müller and later by Epstein. They come to the conclusion that not only does such a disease exist (though it might be preferable to designate it by the name of "Epstein's disease"), but that it is most important that it should be correctly diagnosed, since it is amenable to appropriate treatment—that is, the administration of thyroid extract and a high protein diet.

Myth of Auto-intoxication in Constipated Patients. G. and R. Léven.—p. 1268.

Diuresis in Jaundice.—The authors studied the metabolism of water as indicated by the method of "artificial diuresis" in catarrhal and obstructive jaundice and in the jaundice which accompanies cirrhosis. This is not a test of hepatic insufficiency, but it yields most useful information in regard to water metabolism. It is easy to perform and can be repeated, and is thus essentially a clinical test. In most cases it agrees closely with the galactose test, but in some instances it has shown even closer agreement with the clinical condition than the latter.

- *Treatment of Emaciation in Late Puberty by Transplantation of Pituitary Gland (Ger.). E. Kylin—p. 75.
- Diagnosis of Myocardial Infarction with Aid of Chest Leads (Ger.). R. Langendorf and A. Pick—p. 80.

Three Synchronized Leads.—A method of placing chest leads is described in which the lead sites are chosen at characteristic points on the contour of the projection of the heart by screening. This makes it possible to arrange the leads in planes which practically coincide with the anatomical axes of the heart.

Transplantation of Pituitary Gland.—Observations in thirty-two cases—all females—show that transplantation of the pituitary is the only treatment which promises permanent success. In most of the cases the results were excellent and the restoration to normal was complete. A striking picture of a patient before and after operation illustrates the degree of success obtained.

- Low Serum Glucose in Leukaemic Mice. J. Victor and J. S. Potter—p. 578.

Anti-cancer Preparations.—Three preparations recommended as specific "cancer cures" were investigated—namely, the so-called "Schmidt vaccine"; ensol, which was recently described by Connell and which is prepared by inoculating a tube containing cancer tissue immersed in physiological saline solution with *Bacterium histolyticus*; and a hormone extract, the mode of preparation of which remains a secret. The author studied the effect of these specific "cures" upon actively growing cultures of human malignant cells and of chick embryo, as well as upon mouse sarcoma 180 growing *in vivo*. The author concludes that on the basis of the results obtained from these experiments the Schmidt vaccine, ensol, and the hormone extract of Dr. Jacobs cannot be considered as anti-cancer preparations.

Site of Action of Renin.—Observations on the site of action of the renal pressor substance were made on heparinized rats. The pressor substance was prepared by treating ground renal cortex with alcohol and extracting the precipitate with water. Injection of renin in these animals caused a rise in blood pressure after destruction of the spinal cord and also after exclusion from the circulation of the hypophysis, adrenals, pancreas, liver, and kidney. A vasoconstrictor effect was also demonstrated in the isolated leg. The character of the pressor response was not altered by removing the kidneys immediately before injecting the renin, but the height and duration of the rise in blood pressure were increased in animals in which nephrectomy had been effected two or three days previously.

Effect of Sodium Chloride Deficiency on Gastric Acidity.—A state of sodium chloride deficiency was produced in three normal healthy adult male volunteers by decreasing the sodium chloride in the diet and increasing the excretion of sodium chloride by sweating. A state of sodium chloride deficiency was shown to have been established by the fall in urinary and whole-blood chlorides and by the rise in urea nitrogen and non-protein nitrogen in one of the subjects. Gastric analyses were made each morning and showed that the sodium chloride deficiency produced no significant changes in the gastric secretion in the three subjects studied.

Mixed Tumours of the Lung.—A tumour with the following features is described; eleven cases are cited in detail. It occurs with about equal frequency in the two sexes, is situated near a primary bronchus, usually in the lower lobe, and causes bronchial obstruction early. Microscopically it consists of a fibrous stroma, which may be the only abnormal tissue present in small biopsy specimens, and epithelial cells arranged in alveoli; typical specimens strongly resemble foetal lung. In its early stages the tumour is benign, but it often becomes malignant and should always be regarded as potentially so; in advanced cases where this change has occurred the histological appearance varies and it may be mistaken for several other types of tumour. It is radio-resistant. The authors regard it as of mixed origin, and propose naming it "mixed tumour" of the lung.

- *Fallacy of Systematic Operation for Fibroids. J. Vanverts.—p. 383.
- Sudden Death during Labour. Hartemann.—p. 400.

Fallacy of Systematic Operation for Fibroids.—Attention is drawn to the undoubted clinical facts that fibroids are often completely symptomless, and that neither operation nor x-ray treatment is without a certain degree of risk. It is consequently suggested that before radical treatment is undertaken the patient should be subjected to a long period of medical supervision and treatment, and only when this fails should more advanced measures be adopted. This opinion may be influenced by the prevalent radiation therapy of fibroids, common in France and rare in this country, and productive of so many unfortunate sequelae.

Flexner Dysentery Bacilli.—A serological study embracing many strains of mannitol-fermenting dysentery bacilli leads the author to deny some of the conclusions reached by Andrews and Inman, on whose work is based the serological classification of *Bact. dysenteriae* Flexner which has been accepted since 1919. Types V, W, X, and Z do not possess four antigens in varying proportions, but each has a specific type antigen and a group antigen common to all. The so-called "Y" is not a distinct type, and its frequent recognition is due to the presence of group agglutinin in sera used for identification. Three further distinct types have been identified which possess the same group antigen as V, W, X, and Z, and six others which do not; the latter need further study.

- Analysis of Alcohol-ether Extract of Horse Serum. L. W. Hyman.—p. 71.

Local Immunization.—The agglutinin content of various tissues was determined after immunization by different methods, the material used for these tests being an extract of the tissue made after thorough perfusion in order to rid it of blood. After "general" immunization—that is, parenteral injection—whether active or passive, the ratio of tissue antibody to serum antibody was on an average 1:10. On the other hand, when vaccine was given by nasal instillation and the agglutinin content of the nasal mucosa subsequently estimated the ratio of this to serum agglutinin was on an average 1:5 and occasionally 1:1 or even 2:1. These and other experiments are held to indicate that antibody is formed locally at the site of introduction of a bacterial antigen: Local immunization at the portal of entry of infection should therefore be more effective than the usual method of subcutaneous injection.

- Determination of Sulphanilamide in Blood. J. Kamlet.—p. 1101.

Subclinical Scurvy.—The most accurate method of determining the degree of vitamin C deficiency is by estimating the rate of absorption of an injected dose from the blood stream; the rate of excretion of a test dose, though less precise, is still a dependable method. Among simpler methods estimation of vitamin C in the blood is the most dependable. The capillary resistance test is the simplest; it may give false negative results in the presence of severe anaemia.

 Necessity for Complete Exploration of Bladder before Prostatectomy. Marion.—p. 139.

Chorion Epithelioma of Right Testis.—A case of chorion epithelioma is described. The authors have traced published reports of sixty-four previous cases in the literature, a full bibliography of which is appended to the article. The rapid and extensive metastasis by the blood stream which is so common with these neoplasms is emphasized in the history of the case here reported. A description of the findings at necropsy is given, together with a detailed account of the microscopical appearances of the tumour. The authors also express briefly their opinion upon the prognosis in cases of chorion epithelioma of the testis.

 Report of Five Hundred Blood Transfusions. E. H. Fell.—p. 253.
 Blood Transfusion and Storage of Blood for Emergency Procedures. E. Tuohy.—p. 261.

Delayed Appendicectomy.—The controversial question of immediate or delayed operation in cases of perforation of the appendix is fully discussed. Although it is admitted that delayed operation has never been adopted by the majority of surgeons, the author argues that it is based on sound physiological and surgical principles. Details are given of seventy-seven patients with peritonitis of appendicular origin who were treated conservatively; the results show a reduced mortality.

 Ante-partum Haemorrhage. L. M. Randall.—p. 1159.

Deep Infections of the Neck.—This is a review of 267 patients with deep infections of the neck treated at the Mayo Clinic since 1922. The youngest patient was aged 3 days and the oldest 76 years. The treatment generally employed is described in detail, and the authors advocate strongly early tracheotomy in cases in which there is marked obstruction of respiration due to cellulitis of the neck. Incision and drainage should not be performed until the abscess is well localized. There was no case of mediastinitis in this series, and the mortality from all causes was 3 per cent.

 III: Experiences with Reactions of Bendien and Botelho. R. Merten.—p. 533.
 IV: Results with Rodewald's Inactivation of Melanophore Hormone. W. Rodewald.—p. 540.
 V: Examination of Roffo's Reaction. D. Albers.—p. 543.

Alimentary Tract Tumours produced by Irradiated Cholesterol.—Irradiated cholesterol added to the food of rats produced lesions of the stomach ranging from erosions to adenocarcinomata and highly malignant spindle-celled sarcomata of the liver. Roffo believes that cholesterol is converted by irradiation into a carcinogenic hydrocarbon and that the production of skin tumours by sunlight or ultra-violet light is due to this chemical change.

Diagnostic Value of Biochemical Tests for Cancer.—In the introductory paper Hinsberg discusses the conditions which proposed tests for early cancer should fulfil. His colleagues then report on the examination of several methods for which a high degree of accuracy has been claimed. The reactions of Fuchs, Bendien, Botelho, and Roffo gave too many false reactions to be of value in practice. Under favourable conditions Miribek's modification of Fuchs's test was more satisfactory than the original, and Rodewald obtained 27 correct results in 323 tests with his own method.

★A Capsule a day from now until May

Prescribe Adexolin — the rationally balanced concentrates of vitamins A and D—throughout the winter months. Adexolin builds up a powerful resistance to colds, bronchitis, influenza, and other seasonal infections. For susceptible patients the treatment should be started as early as possible. One Adexolin Capsule a day (or 20 drops of Adexolin Liquid)

is an effective prophylactic dose for adults and older children.

For infants, 2 drops of the liquid should be added to every bottle feed.

Each 3 m Adexolin Capsule is equal in vitamins A and D to 10 cc. of medicinal cod-liver oil. Each cc. of liquid is that in 20 cc. of medicinal cod-liver oil. Capsules: 25, 2 6; 100, 7 6; 500, 30 6; 1,000, 56 1/2. Liquid: 1/2-oz. phials with dropper, 2 6; 2-oz. bottles, 7 6; 4-oz., 12 6; 8-oz., 22 6.

Prices and applicability in India are subject to local professional discount

Why Lactogen so adequately replaces Breast Milk where natural Feeding is deficient or impossible

Scientifically and in actual practice, Lactogen resembles Baby's natural food as closely as is possible. Both the proportions of its food elements and its physiological character are practically identical. The homogenisation process reduces the fat globules to a size even smaller than those of breast milk. The curd is light, flaky and practically unaltered, and the mineral salts are presented in a form. That is why babies who are deprived of their natural food thrive so well on Lactogen.

The Treatment of ANÆMIA

Many cases of anaemia improve more rapidly upon a combination of liver and iron than on either alone.

One tablespoonful represents $\frac{1}{4}$ lb. of whole liver and contains $2\frac{1}{2}$ grains of iron, chiefly in the ferrous state. Most patients like the taste.

IMPORTANT ANNOUNCEMENT

'SUMMIT' Hypodermic Needle now ALL-BRITISH

The sole manufacturing rights of the 'SUMMIT' hypodermic needle having recently been taken over by S. and R. J. Everett and Company Limited, it is now entirely British.

EXCLUSIVE FEATURES OF 'SUMMIT':

(1) EASY TO WIRE.

Cleaning wire can be conveniently inserted through the mount due to a flared cone running down the needle bore.

(2) FIRM SILKY FIT.

Ensured by a soft durable metal seating to a specially reinforced mount (Pat. 7359).

(3) EASY TO ATTACH.

The shape of the 'Summit' mount enables it to be firmly gripped between the thumb and forefinger.

(4) LEGIBLE MARKING.

Owing to the shape and construction of the mount, the needle size is cast on it in very legible characters.

(5) APPEARANCE.

The special metal with which the mount is made retains a perfect appearance throughout the life of the needle.

CRICHTON ROYAL, DUMFRIES

FOR
NERVOUS AND MENTAL DISORDERS.

This Hospital has every facility for complete investigation of the above conditions, and provides all forms of modern treatment including psychotherapy, physiotherapy, occupational and recreational therapy. Cases of alcoholism and drug addiction are admitted. The Physiotherapy Department has separate units for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There are also hot and cold baths, Scotch and Vichy douches, Plombières treatment, electric and Turkish baths, etc. There is a fully equipped gymnasium under qualified instructors. Facilities are provided under special recreational therapists for all indoor and outdoor games, including golf course, croquet, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens.

The Hospital has its own Cinema, Library and Hairdressing Saloon. Terms include regular motor drives. Private rooms, suites or villas are available and special nurses can be provided. The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country and include an extensive farm (117 beds), gardens and orchards.

At the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3, to 30 guineas per week. Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For particulars, apply to the Medical Superintendent.

Medical Superintendent: P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law.
Tel.: Dumfries 1119.

THE MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 3841.

A CLINIC instituted by the London County Council for treatment of Nervous and Mental Disorders. Voluntary patients only are received. New Out-patients.—MEN: Mondays and Fridays, 2 p.m. WOMEN: Tuesdays and Fridays, 2 p.m. CHILDREN: Mondays and Fridays, 10 a.m. In-patients: (a) 235 beds (both sexes) in wards of separate rooms, including 35 beds in a ward of King's College Hospital, which is in use as a temporary annexe of the Maudsley Hospital; (b) special ward (including some private rooms) for those patients of each sex who are paying for treatment, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

Terms include (with rare exceptions) all forms of treatment, for which there are extensive facilities, as there is a staff of Consultant Specialists, and the Central Laboratory of London County Council Mental Hospitals is attached to the Maudsley Hospital. Inquiries to EDWARD MAPOTHER, M.D., F.R.C.P., F.R.C.S., Medical Superintendent.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBIDGE, SUFFOLK**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the
RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 216 (Tell Call from London).

Proprietors: The Norwood Sanatorium, Limited.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders, Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham.

Station: Eden Park (Southern Railway).

Telephone: Springpark 119(-1)

President: VISCOUNT WAKEFIELD OF HYTHE, G.C.V.O.

Treasurer: SIR LIONEL FAUDEL-PHILLIPS, B.A.T.

Physician-Superintendent: J. G. PORTER PHILLIPS, M.D., F.R.C.P.

This REGISTERED HOSPITAL is situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds. Application can be considered on behalf of patients of the educated classes in a presumably curable condition.

With a view to early treatment voluntary or uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.

TREATMENT ON MODERN PRINCIPLES—Every facility for specialised investigation and treatment is provided in the Lord Wakefield of Hythe Science and Treatment Unit, including RADIOLOGICAL and DENTAL DEPARTMENTS, BIO-CHEMICAL, PATHOLOGICAL and PSYCHOLOGICAL LABORATORIES.

The Medical Staff have access to a panel of Consultants in cases which present unusual symptoms requiring specialised investigation and treatment.

Under the direction of qualified officers HELIO-THERAPY, HYDRO-THERAPY and ELECTRO-THERAPY are administered in the Physio-Therapy Department.

INSULIN TREATMENT.—For special cases of mental disorder Insulin Treatment is being carried out with good results and suitable cases are accepted.

OCCUPATIONAL THERAPY, in the form of various Arts and Crafts, is actively encouraged from the medical aspect, and under the guidance of a competent staff this department has proved most effective as a therapeutic factor in all stages of mental illness.

The promotion of physical fitness is a prominent item of treatment, and this is enhanced by arrangements for patients to take part in Outdoor and Indoor Sports and Entertainments, and special attention is drawn to the physical drill and dancing classes which form part of the regular hospital routine.

Application should be made to the PHYSICIAN-SUPERINTENDENT.

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietists, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: THE SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin. *Telephone:* Ruthin 66.

ST. ANDREW'S HOSPITAL^o FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D. M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

Seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast on the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent. Telephone No. 2356 and 2357 Northampton. Who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel. 64117. For terms, etc., apply to the Medical Superintendent.

HAYDOCK LODGE

NEWTON-LE-WILLOWS, LANCASHIRE

LONDON HOSPITAL MEDICAL COLLEGE

THE LIDDLE TRIENNIAL PRIZE.

Under the will of the late Dr. John Liddle, the College Board of the London Hospital offer a prize to the value of £120 for the best essay on "PURPURA—ITS AETIOLOGY AND TREATMENT."

A statement of the rules under which the prize is awarded may be obtained from the undersigned, to whom Essays should be sent not later than May 31st, 1939.

Dr. A. E. CLARK-KENNEDY, M.D.,
F.R.C.P., Dean.

London Hospital Medical College, Turner Street,
London, E.1

The KIRK DUNCANSON FELLOWSHIP FOR MEDICAL RESEARCH

The Council of the Royal College of Physicians of Edinburgh are prepared to award the above Fellowship to the applicant who, in the opinion of the Council, furnishes satisfactory evidence of his ability for medical research.

Applicants must state the nature of the proposed research, the amount of time it is proposed to devote to it, and the place where it is intended to carry it out. If desired, the successful applicant would be granted facilities for conducting his investigations in the Research Laboratory of the College. The value of the Fellowship for the first year will be £350, and a grant for expenses may be allowed. The successful candidate will be eligible for re-election, and at the discretion of the Council the amount of the Fellowship may be substantially increased. Applications must be sent to the Secretary, Royal College of Physicians, Edinburgh, 2, not later than Thursday, December 1st, 1938.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

58, Queen Anne Street, London, W.1.

EXAMINATION for the MEMBERSHIP
—January 3rd and 17th, 1939.

Application for this Examination on the prescribed form should be made not later than November 5th. Candidates whose applications are accepted must submit case records, etc., as required by the Regulations not later than Wednesday, December 14th.

G. F. GIFFERD,
Honorary Secretary.

THE LISTER INSTITUTE OF PREVENTIVE MEDICINE

JENNER MEMORIAL STUDENTSHIP IN VIRUS RESEARCH.
LISTER INSTITUTE RESEARCH STUDENTSHIP IN BIOCHEMISTRY.

Applications are invited for the above two studentships, value £250 per annum, tenable for one year from January, 1939, but renewable, on satisfactory progress, for a second year.

The selected students will be required to work under the supervision of the Staff on problems of virus chemistry and bacterial chemistry respectively. A sound knowledge of organic chemistry is essential and it is desirable that candidates should have had experience in biochemical and bacteriological technique and some training in research methods generally.

Applications, giving full details of scientific training and the names of two referees familiar with the candidate's career, should be sent to the Secretary, Lister Institute, Chelsea Bridge Road, London, S.W.1, before November 30th.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Dr. Harold Scott, C.M.G., will deliver the FitzPatrick Lectures on Tuesday, November 8th, and Thursday, November 10th, at 5 o'clock, at the College, Pall Mall East, S.W.1.

Subject: "Conquest of Disease in the Tropics." Any Member of the Medical Profession admitted on presentation of card.

By Order of the President,
H. M. BARLOW,
Secretary.

Preliminary Examinations

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1.

P. H. ADAMS, Margaret Ogilvie
Reader in Ophthalmology.

W. L. PLATTIS,
Clerk of the County Council.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

Fuller information can be obtained from The Director of Medical Services, Air Ministry, Kingsway, London.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

The Director,
Ross Institute of Tropical Hygiene.

KEPPEL STREET, GOWER STREET, W.C.1.

COUNTY BOROUGH OF HUDDERSFIELD APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered Medical Practitioners (ladies) who have had special experience in ante-natal work and in the care of infants. Salary £500-£25-£700, initial salary according to experience. The doctor appointed will be required to reside in the Municipal Maternity Home when the extensions in progress at present have been completed. A deduction will then be made from the salary for board, etc.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination before being appointed to the position.

Applications, stating age, full particulars regarding training, qualifications, and appointments held since qualification, should be forwarded to the Medical Officer of Health, Public Health Department, Huddersfield, along with copies of two recent testimonials, so as to reach him not later than Thursday, November 17th, 1938.

Application forms are not provided.
SAMUEL PROCTER, Town Clerk.
Town Hall, Huddersfield.
November, 1938.

COUNTY BOROUGH OF SMETHWICK. ST CHAD'S HOSPITAL, BIRMINGHAM, 16 HOUSE SURGEON.

Applications are invited from registered Medical Practitioners for the appointment of House Surgeon at the Council's Municipal Hospital. The appointment will be for a period of six months, with salary at the rate of £150 per annum, with the usual emoluments. If the successful candidate is re-appointed for a further period of six months the salary will be at the rate of £200 per annum. St. Chad's Hospital contains 147 beds, and the cases treated include general medical, acute surgical, and maternity patients. It is staffed by the Honorary Consultants of the Birmingham teaching hospitals.

Forms of application may be obtained from the Medical Superintendent, St. Chad's Hospital, Hagley Road, Birmingham, 16, to whom applications, endorsed "House Surgeon" and accompanied by copies of three recent testimonials, must be delivered not later than November 9th, 1938. Canvassing, directly or indirectly, will disqualify. Council House, FRANK CHAPMAN, Town Clerk.
Smethwick.
October 25th, 1938.

COUNTY BOROUGH OF BRIGHTON. BRIGHTON MUNICIPAL HOSPITAL.

Applications are invited from duly qualified men for the post of SECOND RESIDENT ASSISTANT MEDICAL OFFICER at the Brighton Municipal Hospital.

Candidates must be single men, and preference will be given to those holding an F.R.C.S. or who produce evidence of having had practical surgical experience in a recognized hospital, as the appointment is primarily for surgical work, although not entirely so.

The appointment is for one year, but the person appointed will be eligible for appointment for a further year.

Salary £375 per annum, together with residential allowances valued for the purpose of superannuation at £150 per annum.

Forms of application, conditions of appointment, and list of duties may be obtained from the undersigned, which forms, duly completed and accompanied by copies of testimonials, must be returned to the Medical Superintendent not later than Wednesday, November 16th, 1938.

Canvassing the Committee, either personally or by letter, will be considered a disqualification for appointment.

S. J. FIRTH,
Medical Superintendent
Brighton Municipal Hospital,
Elm Grove, Brighton, 7.
October, 1938.

CHESHIRE COUNTY MENTAL HOSPITAL, Parkside, Macclesfield.

Applications are invited for the post of THIRD SENIOR ASSISTANT MEDICAL OFFICER. Candidates must have had previous mental hospital experience and must hold a diploma in psychological medicine. Preference will be given to those who have had experience as a house surgeon or physician in a general hospital.

Salary £550 per annum, rising by 100 annual increments of £25 each to £690, with house (rent and rate free), coal, electric light, laundry, and garden produce, which are valued for superannuation purposes at £100 per annum.

The appointment will be subject to the provisions of the Asylums Officers' Superannuation Act, 1909.

The hospital has a fully equipped laboratory, clinical and research purposes.

Experience in treatment of out-patients, occupational therapy will be an advantage. Applications, with copies of three testimonials, must be sent to the Medical Superintendent not later than November 9th.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT.—The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE.—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES.—Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health, and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S.W. 1.

BOROUGH OF BLYTH.

RIVER BLYTH PORT HEALTH AUTHORITY.

MEDICAL OFFICER OF HEALTH

Applications are invited for the appointment of a full-time Medical Officer of Health School Medical Officer for the above-mentioned Borough and Medical Officer of Health for the above-mentioned Authority with the necessary qualifications as prescribed by the Sanitary Officers' (Outside London) Regulations, 1935, the Local Government Act, 1933, the Public Health Act, 1936, and any other Acts and Regulations made thereunder, at a salary of £800 per annum, rising by four annual increments of £25 to £900 per annum.

The person appointed will be required to carry out the duties described by the said Regulations and Acts and such other duties as may, from time to time, be prescribed by the Minister of Health or assigned by the Council or authority to the offices.

The successful candidate will be required to reside in the Borough, and the appointment is also subject to the other usual terms and conditions adopted by the Council.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Forms of application may be obtained on application to the undersigned, and completed applications should be endorsed "Medical Officer of Health," accompanied by copies of not more than two recent testimonials, which must be sent to the undersigned not later than November 15th, 1938. Canvassing, either directly or indirectly, will be deemed a disqualification.

Municipal Buildings, J. LEIGH TURNER,
Blyth Town Clerk.

SURREY COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICERS.

Applications are invited for the appointment of Assistant Medical Officers. Applicants must possess a qualification in Public Health. The main duties will be in connexion with the School Medical and Maternity and Child Welfare Services, but the officers appointed will be required to undertake such other Public Health duties as may be allocated to them. They will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote their whole time to the work.

Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointments will be subject to the approval of the Ministry of Health and the Board of Education, to the successful candidates passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, *inter alia*, that appointment may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained and to whom any inquiries relating to the appointment should be addressed.

Last day for receipt of application. Wednesday, November 16th, 1938.

Canvassing, directly or indirectly, will disqualify.
DUDLEY AUKLAND,
Clerk of the County Council
County Hall, Kingston-upon-Thames
November 1st, 1938.

BOROUGH OF WIMBLEDON

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Male).

Applications are invited for the above appointment from qualified and registered medical practitioners under 35 years of age having at least three years' experience since qualification. Applicants should possess the D.P.H., and experience of School Medical work and general public health work is necessary.

The Officer appointed will be required to reside in the Borough, to devote his whole time to his official duties, and to work under the direction of the Council's Medical Officer of Health.

The commencing salary is £600, rising by annual increments of £25 to a maximum of £700 per annum. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the passing of a medical examination.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Wimbledon, to whom they must be returned, with copies of three recent testimonials, not later than first post on Monday, November 21st.

HERBERT EMERSON SMITH, LL.B.,
Town Hall, Wimbledon, S.W. 19. Town Clerk.
November 1st, 1938.

APPOINTMENTS.—Contd.

KING EDWARD VII HOSPITAL, WINDSOR.
(200 Beds)

CASUALTY OFFICER required beginning December. Applicants must be fully qualified men or women and unmarried.

Salary at the rate of £120 per annum, together with board, residence and laundry.

Applications, stating age, qualifications and experience, accompanied by testimonials, should be sent to the undersigned not later than November 16th.

A. E. CHURCHER, Secretary.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA AND OTHER DISEASES OF THE RECTUM.
City Road, E.C.1

Applications are invited for a CLINICAL ASSISTANTSHIP now vacant in the Out-patients' Department on Monday afternoons. The appointment is for six months in the first instance and a fee of three guineas is payable on appointment. Applications to reach the Secretary (from whom further particulars may be obtained) at the Hospital by Saturday, November 12th, 1938.

THE HOSPITAL FOR SICK CHILDREN.

Great Ormond Street, London, W.C.1.

There are vacancies for the following:
A RESIDENT SURGICAL OFFICER. Duties to commence on January 1st, 1939. Salary £200 per annum.

This appointment is tenable in the first instance for one year, but may be extended for a period of one further year.

TWO RESIDENT HOUSE PHYSICIANS and ONE RESIDENT HOUSE SURGEON. Duties to commence on January 1st, 1939. Salaries at the rate of £50 per annum.

These appointments are tenable for six months.
A RESIDENT ANALYSTHIC REGISTRAR. Duties to commence on January 1st, 1939. Salary at the rate of £100 per annum.

This appointment is tenable in the first instance for six months, but may be extended for a further period of six months.

A RESIDENT MEDICAL OFFICER at the Country Branch Hospital, Tadworth Court, Tadworth, Surrey. Duties to commence on January 1st, 1939. Salary at the rate of £250 per annum.

This appointment is tenable for six months, but is renewable.

Candidates for the above appointments must be unmarried, possess a legal qualification to practice, and have held a responsible resident appointment at a General Hospital.

Applications must be received by noon on Monday, November 28th, 1938, and candidates must be prepared to attend for interview by the Joint Committee at 4.45 p.m. on Wednesday, December 7th, 1938.

Full particulars and forms of application are obtainable from the undersigned.

HERBERT F. RUTHERFORD,

November, 1938. Secretary.

MILLER GENERAL HOSPITAL.

Greenwich Road, S.E.10

Applications are invited for the following posts:
HOUSE PHYSICIAN (male, unmarried). Salary £100 per annum.

HOUSE SURGEON (male, unmarried). Salary £100 per annum.

TWO CASUALTY OFFICERS (male), part time, one for morning session and one for afternoon. Salary £150 per annum, non-resident. Fuller particulars on application.

OUT-PATIENT OFFICER, who is required to see Medical and Surgical cases. Attendance daily (except Sunday) from 9 to 11; Tuesday 9 to 5. Salary £150 per annum and lunch.

The appointments are for six months from January 1st, 1939. There are six Resident Officers.

Application forms can be obtained from the Secretary, and must be returned not later than November 21st, 1938.

November 1st, 1938.

MILLER GENERAL HOSPITAL.

Greenwich Road, S.E.10.

Applications are invited for the post of **RESIDENT SURGICAL OFFICER and REGISTRAR** (the senior of six resident posts). Salary £250 per annum. Candidates (male) must be unmarried. Board, residence and laundry provided. Duties to commence on January 1st, 1939.

Application forms can be obtained from the Secretary, and must be returned not later than November 21st, 1938.

November 1st, 1938.

THE CHILDREN'S HOSPITAL—KING EDWARD VII MEMORIAL,

Birmingham, 16.

RESIDENT MEDICAL OFFICER.

Applications are invited for the above post. Candidates must have held a responsible Resident appointment at a teaching Hospital. The salary is at the rate of £175 per annum, with board, residence and laundry. The appointment is tenable for one year, and the Officer is eligible for re-election for a second year.

The present holder has been appointed R.M.O. to the Hospitals Centre. The duties, therefore, are to be taken up on December 1st, 1938, or as soon after that date as can be arranged.

Candidates, who must be fully qualified and registered, should send in their applications to the undersigned within the next week.

HAROLD F. SHIRIMPTON,

October 31st, 1938. House Governor.

THE ROYAL CANCER HOSPITAL (FREE)

(Incorporated under Royal Charter).

Fulham Road, London, S.W.3.

Applications are invited for the two posts of **HOUSE SURGEON**, to commence duties on January 1st, 1939.

Salary at the rate of £100 per annum each.

The appointments are for six months and subject to rules, a copy of which may be obtained from the Secretary.

Applications, to be made on a form which will be supplied by the Secretary, together with three (copies only) testimonials, to be sent to the undersigned not later than the first post on Monday, November 14th, 1938.

CLEMENT COBOLD,

Secretary.

THE ROYAL CANCER HOSPITAL (FREE)

(Incorporated under Royal Charter).

Fulham Road, London, S.W.3.

Applications are invited for the post of **HOUSE SURGEON** (Resident), to be attached to the Radium Department. Candidates must be registered Medical Practitioners. Salary £100 per annum. Facilities afforded for Postgraduate study. The appointment is for six months, commencing December 1st, 1938.

Applications, to be made on a form which will be supplied by the Secretary, with copies only of not more than three recent testimonials, to be sent to the Secretary not later than the first post on Monday, November 14th, 1938.

CLEMENT COBOLD, Secretary.

Gaymer's
TRADE MARK
CYDER

This brand of GAYMER'S CYDER has been recommended as suitable for Diabetics; it contains only the barest trace of sugar (see typical analysis).

Specific gravity	0.9984	Sugars	0.12%
Alcohol by volume	6.46%	Acidity	0.53%
Extract or solids	1.95%	Ash or Minerals	0.25%
Non-sugar solids	1.83%	Original gravity	1.0483

Calories per pint 250
Grams sugars per fluid oz. 0.02

The extract contains metabolisable organic acids, glycerol and sorbitol. The mineral matter is mostly carbonate and phosphate of potash.

FREE SAMPLE ON RECEIPT OF MEDICAL CARD QUOTING "B.M.J."

WM. GAYMER & SON, LTD., ATTLEBOROUGH, NORFOLK

In the treatment of MACROCYTIC ANAEMIAS

This palatable liquid extract of hog's stomach contains Hæmopoietin in stable solution. The stomachs are treated immediately after killing to extract the *Antianæmic Factor in active condition* producing a bland liquid of pleasant flavour, to which the name HOGASTRIN has been given.

A dose of two teaspoonfuls in a little water three times a day for a fortnight, then reduced to one teaspoonful, will invariably give good results in the treatment of all Macrocytic Anæmias.

For inspection sample and literature apply to the manufacturers:

GILES SCHACHT
AND CO.

Do You Know

NELSON NEW LOOSE-LEAF PUBLICATIONS?

NEW PAGES FOR OLD
and **INCLUDING CONSULTATION SERVICE**
THE LIVING ENCYCLOPEDIA which absorbs the **LATEST AND BEST** in modern medical knowledge.

EXCERPTS FROM REVIEWS:

BRITISH MEDICAL JOURNAL: "The purpose of the volumes, with their handy device for insertion and removal of pages from time to time, is to mirror present-day medicine."

LANCET: "Intermediate between new books and new editions comes the monumental 'Nelson's New Loose-Leaf Medicine,' edited by W. W. Herrick, which is kept evergreen by replacements."

LANCET: "We have nothing but praise for this immense well-known surgical system of which the eight volumes contain over 6,000 pages. The whole field of surgery is covered by experts in every branch, and the work has the supreme merit of being always up to date."

BRITISH MEDICAL JOURNAL: "The new method of assembly is a decided improvement upon former binding cover, because a page can be taken out or inserted in any given place."

LANCET: "It is an extraordinary achievement on the part of the editors of this Loose Leaf Surgery to have been able to maintain the production of renewal pages at such a high level for so many years. Assurance of the reliability of this service is the most eloquent of all recommendations of this work to the coming generation of surgeons." "Revised versions have arrived regularly, much of the original has been discarded and replaced, and the present edition is as modern as it possibly could be."

DeLee's Obstetrics—Used the World Over Because of Features Like These

Thoroughly up-to-date following a complete revision.

Includes the new methods and treatments such as use of Willett's forceps, sulphanilamide treatment of puerperal sepsis, and other new measures.

Both medical and surgical.

Especially clinical without slighting important fundamentals.

Authoritative—based on an unusual experience with cases in the home and in the hospital.

Includes concise but full consideration of diseases incident to pregnancy—tuberculosis, diabetes, heart disease, skin and nervous diseases, anemias, etc.

On toxæmias of pregnancy there are 39 pages.

Extensive discussion of extra-uterine pregnancy, displacements of uterus, abortion and premature labour, diseases of breast.

On placenta prævia there are 22 pages, including Willett's scalp traction forceps.

On puerperal infection there are *four full chapters*, including the new treatments, such as sulphanilamide.

Emphasises prevention of accidents and tells how to deal with unusual situations.

Technique of operative obstetrics, including full chapters on Cæsarean section, and induction of premature labour—147 pages.

1,277 illustrations, 271 in colours.

By JOSEPH B. DeLEE, A.M., M.D., Professor of Obstetrics and Gynecology, Emeritus, at the University of Chicago. Large octavo of 1,277 pages, with 1,277 beautiful illustrations on 985 figures, including 271 in colours. 55s. net.

Pp. 1,286 Price 30s. Postage 8d. Abroad 1s. 5d

This standard work has long been unique as an encyclopaedia of reference for the general practitioner. To its wide and general use, sales of over 38,000 copies in the seven previous editions give ample testimony. The new edition has been so thoroughly revised and brought up to date that it has the qualities of a new book. It has been entirely rewritten and reset in a new type and format. It remains a book to which the general practitioner can constantly refer for authoritative information on accepted therapeutic methods.

Eighth Edition 1938

Cabot's

PHYSICAL DIAGNOSIS

Twelfth Edition by **RICHARD C. CABOT, M.D.**, *Professor of Clinical Medicine, Emeritus, Harvard Medical School, and*
F. D. ADAMS, M.D., *Harvard Medical School Course for Graduates*

Pp. xvii+846 Price 22s. 6d. Postage 8d. Abroad 1s. 9d

390 Illustrations

Thousands of present-day physicians have derived their knowledge of physical diagnosis from "Cabot." The new edition has been completely rewritten and enlarged by three hundred extra pages and nearly a hundred more illustrations. All the illustrations are entirely new. The book is now fully representative of modern physical diagnosis, and reflects clearly the mind of an outstanding diagnostician.

THERMOVENT

NATURAL CONVECTION ELECTRIC HEATING

**provides a warm
healthy atmosphere
at a minimum cost**

Heating for the waiting-room calls for convection-type heaters. Thermovent is the only compact and 100% efficient convector and, by virtue of its patented construction, it offers unique advantages:—

- ★ Thermovent warms and circulates the air, giving a pleasant, healthy atmosphere that visitors and patients will appreciate.
- ★ There is no radiation effect and no intense local heat—two feet or twelve feet away the warmth is the same. The element works at black heat—no charring of dust particles and no danger of scorching.
- ★ SPECIAL ELECTRICITY TARIFFS ARE AVAILABLE IN MANY AREAS FOR THERMOSTAT-CONTROLLED THERMOVENT HEATING.

There are inset, portable and floor-standing Thermovents in moulded or steel casings. All types available with built-in thermostat. Prices from £3.12.6. (1 kw). 2 kw. and 3 kw types also available.

For full details write to:—

O.H.V. MORRIS '12'

BRITAIN'S MOST POPULAR TWELVE

DECLARED the writers in the Press: 'an uncommonly successful car,' 'a world-beater,' 'very definitely out of the usual run,' 'remarkable all-round performance.' And the public agreed. Within twelve months the Morris became the most popular '12' in Britain—thanks to its vivid acceleration, 70 m.p.h., its style, roominess and generous equipment. Try this '12' for yourself. You will confirm the verdict of Press and Public and agree that from every point of view, the Morris is the outstanding '12' on the road today.

PURE enjoyment with this filter tip

In du Maurier cigarettes the full flavour of Virginia tobacco can be enjoyed in the certainty that no throat irritants, no "bits" of tobacco, nothing in fact but the pure and fragrant smoke can pass through the filter tip. The five protective layers in the filter tip are there to guard the health of smokers. du Maurier can be bought either cork tipped in the red box or plain tipped in the blue box.

du MAURIER

the perfect cigarette with the exclusive filter tip

SALTAIR SURGICAL SERVICE

Guarantee
 "We guarantee to alter
 exchange or accept the
 return of any appliance
 without cost ordered by
 the Medical Profession,
 if not found suitable
 within fourteen days
 from date of supply."
 Salt and Son Ltd.

The

SALTAIR ARTIFICIAL BREAST

has met with widespread appreciation—

This surgical fitment instantly dispels the depressing psychological sequel which follows amputation of the breast. The patient is freed from that sense of embarrassment which would otherwise eventuate following the loss of the normal figure line. The Saltair Artificial Breast restores that figure line and with it the self-confidence so essential to the patient's future well-being. For this reason the Saltair Artificial Breast has met with widespread appreciation.

The Saltair Artificial Breast is designed so that it cannot in any circumstances slip out of position. Made from finest resilient sponge rubber, it can even be worn while bathing, for it is practically non-absorbent and is easily dried. Beautifully smooth surface, covered flesh silk. Available in various sizes—average weight only two ounces. Can be supplied without brassiere if patient prefers to sew it into her own foundation garment. Special pamphlet post free to Doctors on request.

London Consulting Rooms:

"OAKLEY HOUSE,"

14-18, Bloomsbury Street, W.C.1.

Female Fitters in attendance Monday to Friday.

Orthopaedic Mechanician Wednesdays only.

By Appointment.

SALT & SON LTD BIRMINGHAM 2

To establish a strong positive Iron Balance

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings : 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

This is the formula :

Colloidal Iron Solution ..	84%
Pure Alcohol	5%
Sugar	10%
Flavouring	1%

As an analgesic and sedative

'EUKODAL' (Merck)

(dihydro-oxycodine hydrochloride)

offers the potency of morphine with greater freedom from side-effects and not so marked a tendency to produce habituation. Combined with scopolamine and 'Ephetonin,' 'Eukodal' is issued for use in pre-medication in the 'Weak' dosage in ampoules for intravenous injection, and it has been favourably reported on in this field.

INDICATIONS: Pain generally, such as colic, appendicitis, ileus, migraine, tabes, etc. Also in irritative and inflammatory conditions of the upper respiratory tract.

Eukodal':—

Tablets of 0.005 gramme
Ampoules of 0.01 "

Ampoules of 0.02 gramme

Powder in bottles of 1, 5, 10, 25 and 50 grammes

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

B.M.J., 16 Oct., 1937, p. 753

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of *every day's output*. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamin B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., The Bemax Laboratories (Dept. B.71), 23, Upper Mall, Hammersmith, W.6.

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

FERTITOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

A complimentary box of Fertitol Capsules and brochure sent on request.

MANDECAL

(Compound Calcium Mandelate B.D.H.)

IN THE TREATMENT OF PYELITIS

The value of Mandecal in the treatment of urinary infections is being demonstrated continuously; for example, it is reported that cases of pyelitis, whether acute or chronic, yield with surprising rapidity to its administration, patients with acute pyelitis being free from infection after only two weeks' treatment, whilst chronic infections have cleared up after only a short course, although previous treatments extending over a period of years had failed.

OESTROFORM

For rapid relief of Menopausal Symptoms

'For the nervous and vasomotor symptoms of the menopause, flushings, irritability, nervous depression, indigestion, and sleeplessness, the oestrogenic hormone is virtually specific if employed in adequate and properly spaced dosage. It is effective in both the natural and the artificial menopause . . . '—(Practitioner, October, 1938, p. 377).

DOSAGE OF OESTROFORM

Ordinary cases of menopausal disturbance require an injection of Oestroform 20,000 international benzoate units (in advanced cases 50,000 international

benzoate units) twice weekly. The dose is reduced immediately the symptoms abate, and the optimum dosage by oral administration of tablets that is necessary to keep the symptoms in abeyance is determined.

THE NATURAL MINERAL WATERS OF

KARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act :

- (1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.
- (2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary Organs.

Bottled under Official Supervision at Karlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

VOLPAR

Volpar is the new contraceptive which has been formulated in co-operation with the Medical Sub-Committee of The National Birth Control Association; it is the outcome of nearly ten years' continuous investigation conducted by University research workers under the direction of the Birth Control Investigation Committee.

Laboratory tests have shown that the active principle of Volpar is the most powerful non-toxic spermicidal substance known.

Volpar Gels are soluble, vaginal suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath. They are issued in screw-capped glass tubes containing 1 dozen gels : price, 2s. 0d. per tube.

Volpar Paste is a non-greasy paste for the lubrication of occlusive caps and sheaths or condoms. It is supplied in collapsible tubes : price, 2s. 0d. per tube.

Volpar Gels and Volpar Paste are sold to the public only through the retail pharmacist.

MARMITE

YEAST EXTRACT
 for vitamin B complex
 in POLYNEURITIS

The close connection between polyneuritis and vitamin B₁ deficiency is well known. Not only is the polyneuritis of 'beri-beri' considered to be due to deficiency of this factor, but so also is the polyneuritis associated with gastro-intestinal lesions, pregnancy, alcoholism and other toxic conditions.

Clinical tests have proved beyond doubt that Marmite therapy is effective in these cases of polyneuritis of nutritional origin. In a recent paper on peripheral neuritis, associated with pyloric stenosis and deficiency of vitamin B₁, it is recorded that the patient

"was advised to take Marmite, 2 drachms daily . . . made a gradual improvement and returned to work . . . still takes Marmite. . ."

(Lancet, May 7th, 1938, p. 1045.)

ALASIL

Better Salicylate Therapy

WHATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication.

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl-salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic, and sedative of established value.

A supply for clinical trial with full descriptive literature sent free on request.

A major operation in progress in the operating theatre of a London Hospital.

DEGREES OF PROTECTION....

THE most elaborate precautions against every possible chance of germ infection are of course essential in the operating theatre. It would be ridiculous, however, to expect anything approaching this meticulous attention to antiseptic cleanliness in everyday hygiene and in the home treatment of superficial wounds.

The general public is nevertheless beginning to realise the importance of germ-free cleanliness. Hygienic standards to-day are higher than they have ever been. It is generally agreed by medical men that although regular use of antiseptics is not desirable or really necessary for ordinary toilet purposes, the use of a reliable antiseptic soap can play a very valuable part in the prevention of infectious disease. Face and hands are continually exposed to infectious germs, and require washing with Wright's Coal Tar Soap.

Wright's has substantial antiseptic and antipruritic qualities. For over 70 years it has enjoyed the confidence of the medical

profession, and to-day more doctors use Wright's than any other brand of toilet soap. Wright's Coal Tar Soap is prepared from materials selected after stringent tests. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable dermatological therapeutic recommended by skin specialists the world over. In surgeries, hospitals, nursing homes and private households Wright's meets all the requirements of modern everyday hygiene. You can use it and recommend it to your patients with complete confidence.

COAL TAR SOAP**

The Safe Soap

Wright, Layman & Umney Ltd., 44-50 Southwark Street, S.E.1

COD LIVER OIL

DOSAGE AND VITAMIN CONTENT

—THE OFFICIAL RULING

Many practitioners have found that their patients still believe it necessary to take large doses of cod liver oil, and in consequence resort to other liver oils of uncertain origin and widely varying vitamin content. Reference, however, to the latest Addendum (1936) of the British Pharmacopoeia shows that the standard dosage for cod liver oil is very much smaller than conventionally supposed, and, moreover, that a definite vitamin content and origin are specified.

The ruling on vitamin content is that each gramme of cod liver oil shall contain not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin B. Given this content, the minimum dose of cod liver oil is fixed at 15 minims (a quarter teaspoonful) three times a day.

The advantages of being able to prescribe a cod liver oil which is guaranteed to conform to this ruling of the British Pharmacopoeia are obvious. The smaller dose is readily acceptable by the patient, which fact makes it unnecessary to resort to other liver oils whose vitamin contents are uncertain both as to origin and efficiency and which have none of the proved food values of cod liver oil.

'SevenSeas' Cod Liver Oil is guaranteed to conform to the British Pharmacopoeia requirements, and it has the additional advantage of being made from absolutely *fresh* livers. The small dose of cod liver now needed and the pleasant taste of 'SevenSeas' Cod Liver Oil arise from the fact that 'SevenSeas' trawlers

are equipped to render the oil on board, immediately the fish are caught. This is possible only with cods' livers, owing to their high percentage of oil. It cannot be done with the livers of other fish.

In the case of 'SevenSeas' High Potency Oil, the dosage is reduced to a matter of drops only, for this oil has a guaranteed vitamin content of four times British Pharmacopoeia standard. It is not concentrated or fortified in any way, but is obtained simply by selection from fresh cod livers with a naturally high vitamin content. This High Potency Oil should be of particular interest to practitioners wishing to prescribe for patients who cannot assimilate fat or have a tendency towards acidosis.

All 'SevenSeas' oil is thoroughly tested before being issued to the public. It is prepared and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in capsules will be sent on request.

Intestinal Disorders consequent upon Bronchial Infection

Partly owing to the considerable amount of sputum inevitably swallowed by the patient in bronchial affections (especially in children), disorders of the digestive organs may be produced.

A suitable diet and a free daily evacuation tend to prevent these disorders.

Andrews Liver Salt by its effervescence freshens the mouth (often so dry in bronchitis) and by its antacid reaction counteracts gastric catarrh. By producing an easy evacuation, safe even in the presence of myocardial degeneration, it removes the organisms introduced by the swallowed sputum.

★ *N.B.—A large size tin will be sent free on request to any member of the medical profession.*

ANDREWS LIVER SALT

SCOTT & TURNER LTD.,
Works and Laboratories at Newcastle-on-Tyne.

HOW WHOLE WHEAT CRISPBREAD BENEFITS HEALTH

WHEAT has always been Man's first choice among the cereals, whenever climatic conditions did not prevent his getting it. That remains true of all bread, either white or wholemeal, either soft or biscuit-crisp. And Vita-Weat, the wheaten crispbread with the WHOLE of the wheat left in it, has advantages which entitle it to a very high place among the staple foods of the world.

Its Calorific Value

Bread is the 'energy component' and Vita-Weat, since it contains only 3 per cent. of water, has a fuel-value nearly twice that of ordinary bread—according to the *Practitioner* its calorie value is 2,132 per lb.

Each section of such a crispbread—each 'slice,' so to speak—has a calorie value of 37. That is to say, that in meeting what is probably the greatest requirement of a national staple food Vita-Weat is almost twice as effective as the softer kinds of wheaten bread.

Starch and Digestion

A crispbread, obviously, calls for a more thorough chewing than a soft 'crumb' bread and salivation is therefore more healthily promoted. The starches and cellulose in Vita-Weat are also 'converted' into a more digestible form by the special processes which go to make a good crispbread—just as toast and crust have become greatly more digestible than bread in its quite 'unconverted' starchy form. While all the wheat-berry is used the bran and fibre are thoroughly disintegrated.

The result is, therefore, that the weight which quantities of 'unconverted' starch places on the digestion is almost entirely eliminated where Vita-Weat has been prescribed.

VITA-WEAT AND ITS ADVANTAGES

In addition to these great advantages of superior fuel-value and digestibility Vita-Weat retains the 'protective' elements of the wheat-berry which are frequently rejected in the 'refining' of white flours. Proteins, vitamins and minerals in which bread is normally deficient are present and the 'balance' of this crispbread as a food is therefore increased. The use of Vita-Weat can be shown to be especially desirable in cases of mild anaemia, liability to infection, lack of appetite, poor digestion, diabetes, obesity and as a food of 'protective' value to the teeth.

A little booklet has been prepared for the medical profession briefly summarising the medical case for a whole wheat crispbread and it will gladly be sent post free to any doctor on application to Peek Frean & Co. Ltd., Keetons Road, London, S.E.16

	CALORIES PER OZ.	17.0

A typical example of the high nutritive values retained in Heinz Strained Foods. (Figures show percentages on the wet basis)

Vegetable and fruit purées, rich in mineral salts, vitamins and other soluble nutriment, constitute the perfect diet for infants and cases of nutritional anaemia.

But despite the wide approval shown by physicians, and a growing appreciation of this dietary by mothers, progress has hitherto been slow, owing to the practical difficulties encountered in home preparation.

The use of vegetables not truly fresh, mechanical losses through oxidation when boiling, and inefficient sieving out of the harsh fibres, inevitably impair the quality of the home-produced preparation.

Now, with the marketing of a range of strained foods by H. J. Heinz Co. Ltd., vegetable and fruit purées containing all necessary dietetic values are available in convenient bulk and form.

Heinz Strained Foods are prepared with all the advantages of the best factory method. The vegetables are specially grown in those areas where soil and climate combine to produce the best; they are harvested when they are just right, and cooked within a few hours of being garnered.

First, the ingredients are scrupulously cleaned. Cooking by light steam pressure in vacuum containers follows, leaving the contents perfectly disposed for comminution by extrusion, and at the same time ensuring retention of the essential juices and mineral constituents. Fine sieving having removed all fibres of a harsh or irritant nature, the purée is then adjusted to an acceptable consistency and sealed in vacuo, the sealed containers being immediately subjected to sterilization under constant conditions of time and temperature.

The purées thus offered are uniform, convenient and of the highest possible nutritive content.

NOTE: *Glass containers are not used owing to the deleterious effect of light on the value and palatability of the purées.*

'Elastoplast' elastic adhesive Plasters are rolled with the adhesive surface *inwards*;

they are clean to handle and to apply, and very convenient when short lengths only are required.

'Elastoplast' Plasters consist of lightweight cotton cloth, spread to the edges, flesh-coloured and rolled on snap spools. They are designed for use as plasters or as dressings for wounds, operation incisions, skin affections, etc. Supplied in all widths from $\frac{1}{2}$ " to 4", $\frac{5}{6}$ yards long.

'Elastoplast' elastic adhesive Bandages are rolled with the adhesive surface *outwards*

to conform with accepted bandaging technique

Made from heavy cotton cloth, selvedge-edged, rolled on card cores, they are suitable for use as bandages for varicose legs, sprains, dislocations, fractured ribs and other cases where complete encirclement of the limb or trunk, with compression, is necessary. Supplied in all widths from 2" to 6", $\frac{5}{6}$ yards long.

NOTE: If specially required, 'Elastoplast' Bandages can be supplied with the adhesive inwards.

Elastoplast BANDAGES & PLASTERS

HEPARIN AND THROMBOSIS*

BY

CHARLES H. BEST, M.A., M.D., D.Sc., F.R.S.

Professor of Physiology, University of Toronto

(WITH SPECIAL PLATE)

While a search of the earlier literature reveals the fact that several investigators realized that certain mammalian tissues contain one or more anticoagulants, an active fraction was first isolated in Howell's laboratory in 1916 (McLean, 1916; Howell and Holt, 1918). Howell named the substance "heparin" (*hepar*—the liver), and he and his collaborators have studied its distribution, chemical properties, and physiological significance. For some time heparin was prepared exclusively from the liver tissue of the dog, and it was very difficult to secure sufficient amounts of a product satisfactory for physiological experiments.

In 1928 Dr. McHenry and I, desiring to use heparin in our histaminase work, found it possible to prepare active fractions from ox liver, and subsequently Charles and Scott (1933a) showed that this substance was present in varying amounts in a great many tissues of this species—lung, liver, and skeletal muscle—giving, in this order, the best yield.

Action of Heparin

Under certain conditions, as Howell originally showed, heparin acts as an antiprothrombase, but in other more physiological circumstances it is apparently an anti-thrombase. The finding of Professor John Mellanby (1934) that the action of a very potent thrombase added to plasma can be inhibited by heparin has been confirmed in my laboratory by Mustard and Jaques (1937). In these circumstances heparin is apparently an antithrombase. Heparin can, of course, be titrated against thrombokinase with considerable accuracy under appropriate conditions, so that thrombokinase may be termed an antiheparin or, conversely, heparin an antikinase. The product described by Charles, Fisher, and Scott (1934) and tentatively termed "antiheparin" turned out to be a typical thrombokinase (Ridout and Best; see Charles, Fisher, and Scott, 1934).

Recent Work on Heparin

The work on heparin in Toronto was started in the department of physiology in 1929. At that time only crude material was easily available, and any advance along physiological or therapeutic lines appeared impossible until a much more highly purified preparation was at hand. Furthermore, although it was known that heparin was an anticoagulant, its action on thrombus formation had been explored only to a slight extent. In one paper Shionoya (1927a), working at the Mayo Clinic, stated that an adequate dose of heparin did not prevent the formation of white thrombi, and this is certainly true when crude heparin is used in rabbits. He subsequently reported

(1927b) that magnesium sulphate markedly retards thrombus formation in the heparinized rabbit.

PURIFICATION OF HEPARIN

Studies in purification were begun at my suggestion by Dr. Arthur Charles, a young organic chemist, in the department of physiology. Charles was presently transferred to the physiological and biochemical section of the Connaught Laboratories, where he had the privilege of working with Dr. D. A. Scott, whose studies on the crystallization of insulin and the preparation of protamine-zinc-insulin are well known to many. Charles and Scott (1933b, 1934, 1936) soon attained success in the purification of heparin, and before very long they evolved a process for the preparation of adequate amounts of satisfactory material from ox lung. Finally, a crystalline barium salt of uniform potency was obtained. An amorphous benzidine compound was also secured which gave the same empirical formula ($C_{10}H_{10}O_8N_2S_2$). I shall refer to this compound later.

The crystalline product contains nitrogen, a part of it at least in the form of NH_2 groupings, upon the inactivation of which the potency of heparin is lost. (Howell thought that his purified product was free of nitrogen.) Jorpes (1935), using purified heparin made by the Toronto procedure, noted the presence of sulphuric acid groups in the molecules, and there is some evidence that the loss of this grouping also may interfere with the activity. Tests for carbohydrate are positive but do not indicate the presence of glycuronic acid, which some previous observers had thought was present. An adequate discussion of the chemistry of heparin should, of course, include detailed references to the interesting and very important contributions made by Schmitz and Fischer, Jorpes, Chargaff, and others, but I must proceed with more physiological matters.

Charles has shown that when the crystalline barium salt is treated with excess of ammonium carbonate solution at 65° C. the barium may be completely removed. The heparin is then precipitated by acetic acid, centrifuged out, washed with ether, and dried. It can be stored as a dry powder. When required a solution can be made from this; trisecol may be used, and the solution sterilized by passing through a Berkefeld or Zeitz filter.

STANDARDIZATION OF HEPARIN

This brings me to a necessary digression—a consideration of the standard of heparin. We have suggested quite recently (Charles: see Murray and Best, 1938) that the material from the crystalline barium salt may be used as a standard. In a very informal discussion with Sir Henry Dale we agreed that it might be wise to make the standard available, if need should arise, as a solution.

* A lecture delivered at University College, London, on June 14, 1938.

I will not discuss here the various physiological methods for the standardization of heparin. They depend on the inhibition of the clotting of blood under certain conditions. A unit has never been defined exactly. It is usually stated to be the amount of anticoagulant which inhibits for twenty-four hours the clotting of 1 c.cm. of blood under certain conditions of temperature and so forth. We have suggested as a provisional unit the activity contained in 0.01 mg. (10 γ) of the barium-free material—that is, 100 units per mg. This would make a convenient unit from both the physiological and the clinical aspect.

A standard of heparin would not only be advantageous from the point of view of those interested in its action, either experimentally or clinically, but would also be of great service to anyone working on any aspect of blood

FIG. 1.—Intravenous injection of heparin. (From Jaques, Charles, and Best.)

clotting. We can standardize thrombase or thrombokinase against the standard heparin, and thus help to bring order out of a very confused field. More standards—for thrombase and thrombokinase—are urgently needed.

ADMINISTRATION OF HEPARIN

If a single dose of heparin be given intravenously the clotting time becomes prolonged. The increase in the clotting time depends on the size of the dose (Fig. 1). There is no negative phase—that is, the clotting time does not go below normal after a massive dose of heparin: it comes back fairly accurately to the initial value. Heparin can be given subcutaneously as well as intravenously. The crude material first used was not well absorbed, but purified heparin is absorbed quite rapidly from the tissue spaces, and a good effect can be obtained

as a result of subcutaneous administration. In the rat the effect of one subcutaneous dose may be to send up the clotting time to over twenty-four hours; the return to normal occupying from twelve to twenty-four hours or longer (Fig. 2). However, two out of sixty experimental animals died as a result of haemorrhage into their subcutaneous tissues after the administration of heparin. There was not a great deal of haemorrhage, but 2 or 3 c.cm. is a large amount of blood for a rat. It is possible that the damage produced locally would not be sufficient to cause a dangerous or even a serious amount of bleeding in large animals.

When heparin is precipitated with protamine a very insoluble compound is formed which cannot readily be suspended (Best, Charles, and Cowan, 1937). With benzidine, however, a compound can be prepared which is absorbed quite slowly and gives a clotting time of ten

FIG. 2.—Subcutaneous injection of heparin. (From Jaques, Charles, and Best.)

FIG. 3.—Subcutaneous administration of benzidine-heparin. (From Jaques, Charles, and Best.)

to fifteen minutes for quite long periods (Jaques, Charles, and Best, 1938) (Fig. 3). It was found advisable to have a little unmodified heparin in the mixture, as certain doses of benzidine-heparin given alone will have no effect at all, but if given with the unmodified heparin the immediate and the prolonged action are both forthcoming.

The best procedure in the administration of heparin is to give a small dose intravenously and to follow this with a constant intravenous injection. The clotting time can be set at any chosen level and maintained for long periods. In experimental animals we commonly give 40 units per kg. as the initial dose, and follow this with a continuous injection of 30 units per kg. an hour. With this dosage the clotting time is usually maintained at from twenty to thirty minutes. Somewhat smaller doses are used by Dr. Murray and his colleagues in the department of surgery.

Studies in Relation to Thrombi

We have carried out a number of studies on heparin in relation to the formation of thrombi. In the first series Murray, Jaques, Perrett, and I (1937) wished to determine the effect upon the mixed thrombus produced when the internal surface of veins is injured. This injury was produced in the first series of experiments by mechanical means, such as clamping the vessel repeatedly with strong forceps. In the second series chemical means were used. A section of the vein was isolated and sodium ricinoleate was injected into the lumen. It was allowed to remain for a few minutes and the blood was then permitted to flow again. After both these procedures a thrombus forms in a large percentage of the cases. Heparin was administered continuously to unanaesthetized dogs for seventy-two hours after the injury had been produced, and healing of the surface of the veins was found to take place in this time with no tendency for thrombi to occur subsequently. The fact that in the best series of experiments (see Table)

No.	Control		Heparin		Heparin u. lb. hr.	Hrs. Heparin given	
	Occluded	Patent	Occluded	Patent			
65	1	1					0.15 cern Soricin injected in all veins Control 17% patent Heparin 100% patent
69	2	-					
70	4	-					
72	2	-	-	2	10.3	63	
73	-	-	-	4	10.9	73	
74	1	1	-	2	10.5	72	
75	-	-	-	4	10.0	72	
Total	10	2	83%	12	-	-	

(From Murray, Jaques, Perrett, and Best.)

all the heparinized veins were open means that they were found in this state a week, usually, after the injury. Heparin, however, had been given for only three days.

STUDIES ON THE FORMATION OF WHITE THROMBI

These results were encouraging, but we wished to determine the effect of heparin on the formation of white thrombi. It is well known, of course, that the white thrombus is the nucleus from which the mixed thrombus grows. In certain conditions a thrombus is obtained which consists entirely of platelets, and it was interesting to determine the effect of heparin on this process. To do this the procedure evolved by Rowntree and Shionoya (1927) of the Mayo Clinic was followed. A cellophane shunt between the femoral artery and the femoral vein was made and the blood was allowed to flow for a certain time. Then the cellophane tube can be sectioned to determine whether any thrombi have formed (Fig. A on Plate). This was carried out on quite a large series of animals—monkeys, dogs, cats, and rabbits (Best, Cowan, and MacLean, 1938). In the rabbit it was difficult to observe the effect; although the tube never became occluded, small specks of thrombi could be seen in spite of the presence of heparin. There was no doubt, however, that in the case of the monkeys, dogs, and cats the action of heparin was to prevent the formation of the white thrombi. These, of course, are admittedly artificial conditions: the blood flowing over the glass and cellophane tubing favours the formation of thrombi, and one

cannot conclude from the dose of heparin required in these cases how much would be needed to prevent a similar phenomenon inside the blood vessel.

HEPARIN AND CORONARY THROMBOSIS

Another line of approach to this problem is the study, in which Dr. D. Y. Solandt and I (1938) have spent a large part of our time this year, of the formation of thrombi which may be produced in the coronary artery of dogs. It is possible by dissecting out the left coronary artery in the dog to obtain a length of half an inch or so, to clip off all the branches, and put two clamps on the main stem a quarter of an inch apart. Then, by introducing sodium ricinoleate into the lumen of the vessel and leaving it for five minutes enough irritation is produced to cause thrombi to form. In a comparable series of animals in which this procedure was carried out and the animals were heparinized just before the sodium ricinoleate was injected a thrombus occurred in only one case. In other words, with this isolated exception, heparin prevented the formation of thrombosis of the coronary artery in the same way as it did in the peripheral veins. We were led to study the coronary artery because of the relatively high frequency of thrombosis of this vessel in the human species and also because it is apparently much easier to get a thrombus in the coronary artery in dogs than in some of the other arteries.

My collaborators and I have thus carried out four investigations which may be listed as follows: mechanical injury to veins, chemical injury to veins, formation of white thrombi, and the studies on the coronary artery. In each case an effect of heparin in preventing thrombosis could be demonstrated.

[Professor Best then projected a coloured film, the first part of which showed the flow of blood through a glass cell introduced between the carotid artery and the jugular vein of the monkey. The rapid formation of white thrombi was well illustrated, and the breaking off of large masses to form emboli. The growth of the thrombus downstream could be clearly seen. The thrombi tended to form in the periphery of the cell, where the flow is slowest, but also on a scratch in the axial stream where the flow was very rapid. The action of heparin in preventing the formation of white thrombi was demonstrated. In the second part of the film the passage of a plasma containing platelets but very few other cells through a small glass perfusion chamber was shown. The clumpings of the platelets could be clearly seen, together with the formation of the digitations. (Figs. B and C on Plate.)]

Use of Heparin in Physiological Experiments

I should like now to speak on the use of heparin in physiological experiments. It is obvious that there are a great number of things which one can do if adequate amounts of the purified material are available. For example, my colleague Dr. D. W. G. Murray has studied, among other problems, end-to-end anastomoses of blood vessels. This can, of course, be done without heparin, but the percentage of successful results is much greater when heparin is used.

Another illustration of the use of heparin is in so-called "exchange" transfusion in experimental animals. This subject has recently been studied by Thalmer, Solandt, and myself (1938). In one experiment, for example, a nephrectomized dog in which the blood urea had become very high was joined by means of a pump, which enabled exchange to be made in each direction of the same amount

of blood, to a normal donor. The result was a precipitate fall of blood urea in the nephrectomized animal and a rise in the normal donor (Fig. 4). (One can bring the blood urea of the nephrectomized animal very quickly back to the normal limits if several donors are used, because the kidneys of the normal dogs do double duty and excrete urine for both.) Both animals were, of course, heparinized. I do not suppose that these findings have any obvious application to clinical medicine, but those of us who are medically trained have visualized very exceptional circumstances in which a completely anuric child might be joined for a few hours to a parent, both being

FIG. 4.—The fall in urea of a nephrectomized animal during "exchange" transfusion. (From Thalheimer, Solandt, and Best.)

heparinized. The clinician, however, who would have to take the responsibility in a situation of this kind might have different ideas on the subject.

Neutralization of Heparin by Protamine

Some years ago it was shown that protamine is an anti-thrombase (Waldschmidt-Leitz, Stadler, and Steigerwaldt, 1929). If protamine be added to the blood the clotting time goes up because of the antithrombase action of the substance introduced. About eighteen months ago Charles, Cowan, and I (Best, Charles, and Cowan, 1937) published a paper in which we showed that heparin and protamine formed a very insoluble compound which could not easily be resuspended. More recently it has been shown by Chargaff and Olson (1937) that if heparin be given to an animal and be followed by protamine the effect of the heparin may be completely neutralized and the clotting time brought back to normal with great rapidity. This has been confirmed by Jaques and myself. Many results can now be brought forward in confirmation of the fact that protamine can be used to neutralize the effect of heparin *in vivo* and *in vitro* (Fig. 5).

Physiological Significance of Heparin

The first piece of evidence in favour of the view that heparin plays a physiological part is obtainable from a study of its distribution: the work of Howell, and subsequently that in Toronto and elsewhere, has shown its presence in various tissues, including blood. Again, the recent work by Jorpes, Holmgren, and Wilander (1937)

(see also Holmgren and Wilander, 1937) along histological as well as chemical lines has shown its presence in particularly large amounts in the mast cells of Ehrlich, and has suggested the possibility that these cells are responsible for its production. A third point has been brought out by Waters, Markowitz, and Jaques (1938) in my department—namely, that there is a good deal of evidence

FIG. 5.—Neutralization of heparin by protamine. (From Jaques, Charles, and Best.)

that the increased clotting time seen in anaphylactic shock in the dog is due to the liberation of heparin. This has been shown also to hold good for peptone shock.

It has been known for some time that histamine, while it may account for many of the signs of anaphylaxis, has little or no effect upon the coagulability of the blood (Dale and Laidlaw, 1911). When a dog goes into anaphylactic shock there is a very great rise in clotting time—that is, from four to five minutes to perhaps forty-eight hours. This was originally shown by Biedl and Kraus (1909). Samples of the blood can be taken and treated with protamine, and the heparin equivalent estimated by this procedure. The results of experiments of this kind carried out by Jaques and Waters are shown in Fig. 6. These results show that heparin in a concentration of approximately 1.5 units per c.c. has appeared in the blood of the animal in anaphylactic or peptone shock. This amount of heparin is sufficient to raise the clotting time of the blood from the normal value to such extremely high levels—sixty to seventy hours—that it may be termed incoagulable. When an animal was shocked after hepatectomy, Waters, Markowitz, and Jaques found little or no rise in the clotting time of the blood or in the heparin equivalent. Furthermore, these workers have obtained from the blood of the shocked animal much more heparin than can be detected in the blood of the normal animal, while the liver of the shocked animal contains less heparin than normal liver. The physiological and chemical results provide practically conclusive evidence that the anti-coagulant isolated from the blood of the shocked animal is heparin, and it may be possible to prepare this material

as the crystalline barium salt. It appears, therefore, that in anaphylactic shock in dogs histamine, heparin, and possibly other substances are liberated.

FIG. 6.—Liberation of heparin in anaphylactic and peptone shock in dogs. (From Waters, Markowitz, and Jaques.)

We may conclude that several points of evidence now suggest the possibility that heparin is a substance of physiological importance.

The Possibility of Clinical Application

As soon as more highly purified preparations of heparin became available investigations were begun in the department of surgery under the supervision of my colleague Dr. D. W. G. Murray. It was found that none of the preparations available except that which had been through the stage of the crystalline barium salt could be given with complete safety. The fact that this highly purified material can safely be given to human subjects over long periods is well established by the findings on some 350 patients, most of whom had experienced a major operation before heparinization was started (Murray and Best). The intravenous administration of heparin is never begun earlier than two or three hours after the completion of a major operation—a splenectomy, for example—and is continued until the patient is able to move actively about in bed. This may be for three or four days, or it may extend to weeks.

It is of great interest that workers in Sweden (Crafoord, 1937; Hedenius, 1937; Holmin and Ploman, 1938; Magnusson, 1938), using heparin prepared by the method elaborated in Toronto, have initiated clinical studies on the prevention of thrombus formation.

It is hopeless to attempt to secure information regarding the effect of heparin in the prevention of thrombus formation by the indiscriminate heparinization of post-operative cases or by the heparinization of isolated cases. This has not been attempted in Toronto. Murray and McKenzie are selecting, in so far as is possible, those cases in which the hospital statistics show that the inci-

dence of post-operative embolism is relatively high. I suppose the best type of case to study would be those exhibiting that rather rare condition known as phlebitis migrans. If it were possible to collect a group of these cases in one ward and to have them thoroughly studied before and after the administration of heparin a great deal might be learned.

A few words may be said with regard to the practical application of the work on coronary arteries in dogs. If the clinical cardiologist knew when thrombosis was about to occur—that is, if there were definite premonitory signs—he might by the appropriate use of heparin secure a short reprieve, perhaps even a long one, for some of his patients. The material is readily available, and can apparently be given safely to hospitalized patients; but our lack of knowledge, or perhaps the complete absence of premonitory signs, makes it impossible to conduct a clinical investigation along these lines. Heparin might be given immediately after one attack of coronary thrombosis, but clinicians do not speak with a single voice when discussing the spread of thrombosis from the original focus or the significance of intramural thrombi formed as a result of coronary thrombosis. If a clinical investigation of cardiac cases should be initiated, the necessity for studying very large numbers and of heparinizing only alternate cases is obvious.

One of the best methods of determining the clinical role of such a substance as heparin is to push ahead with more studies along physiological and experimental pathological lines in the hope that the clinical applications will become obvious. It is true, of course, that many of the experimental conditions which have been studied are not closely related to those observed in the clinic, but the results have been very stimulating, and one hopes that investigations along these lines will be pursued.

I should like to thank Professor Lovatt Evans for his invitation to lecture on this subject in his department.

THORACOSCOPY IN DIAGNOSIS

BY

F. G. CHANDLER, M.A., M.D., F.R.C.P.*Physician, St. Bartholomew's Hospital;
Senior Physician, London Chest Hospital*

(WITH SPECIAL PLATE)

The exact nature of an intrathoracic tumour is often very difficult to determine, but in recent years considerable help has been obtained from the skiagram, stereoscopic skiagrams, the tomogram, the bronchogram, and from bronchoscopic examination, and with these ancillary diagnostic aids it is true to say that in the majority of cases of bronchial tumours an accurate diagnosis can be made, and, furthermore, this type of tumour constitutes the large majority of intrathoracic growths. Nevertheless, there still remain the tumours arising from the mediastinum, from the pulmonary tissue or bronchioles, or from the chest wall, and secondary tumours, in the diagnosis of which the above-mentioned diagnostic measures often, and indeed usually, fail to establish their exact nature. In fact, in these cases the skiagram may be misleading, for the rounded, smooth, sharply defined outline of some of them often suggests an innocent tumour such as a dermoid or a fibroma, etc., but the subsequent history or investigation has proved many to be malignant. Even after the induction of a diagnostic pneumothorax the appearances may still be deceptive.

During the last decade there has been a very great advance in thoracic surgery, and, because of this, accurate diagnosis of these tumours has become more and more important; for if they can be proved to be innocent growths or growths lying free in the thoracic cavity, or even if they are malignant growths—provided they are confined to a single lobe, are discrete, and are not invading the mediastinum—surgical intervention can be expected to offer the prospect of a cure.

In spite of the great improvement in technique it cannot yet be claimed that an exploratory thoracotomy has reached the degree of benignity that is associated with an exploratory laparotomy, and, therefore, for the above reasons, when we have had to deal with such tumours we have endeavoured, by inducing an artificial pneumothorax and subsequently introducing a thoracoscope into the pneumothorax cavity, to ascertain the exact nature and extent of the growth, and, if possible, to remove a piece for section. At the same time it has also been possible to establish the precise anatomical relations of the growth, thus giving much help to the surgeon in planning his line of approach at the subsequent operation, a detail which may determine the success or failure of the operation; for, with the exception of cerebral surgery, there is probably no other branch in which the question of the approach to the operation is of such vital importance.

The method was first described in English in March, 1922, in the epoch-making paper by Jacobaeus and Einar Key in *Surgery, Gynecology and Obstetrics*. Since then further observations have been made and certain appearances recorded, but on the whole it has not received the attention it deserves. One reason perhaps is that fluid, either serous or haemorrhagic, may complicate the field, and although completely replaced by air the previous deposition of fibrin may obscure landmarks and all detail.

Even with fluid, or even with blood, this is, however, by no means always the case, and where there is no fluid and a diagnostic artificial pneumothorax is induced everything stands out with amazing clearness.

We believe that the cases which we are describing in this article demonstrate the value of diagnostic thoracoscopy.

Case I

A man aged 36 was admitted to the London Chest Hospital in February, 1930, complaining of blood-stained sputum. There was marked clubbing of the fingers. On the left side of the chest absolute dullness was found from the fifth rib downwards. Breath sounds were faint, and there was some pleural rub. The skiagram revealed a discrete rounded mass in the left lower lobe; the true lateral skiagram showed an oval sharply defined mass lying posteriorly. The Wassermann reaction and hydatid tests were negative. The white blood cells numbered 16,000 per c.mm., with 74 per cent. polymorphs. No tubercle bacilli were present in the sputum.

A pneumothorax was induced, and the lung, contrary to what we hoped, appeared to fold itself, as it were, around the mass. A thoracoscope was passed into the fifth space in the mid-axillary line. The surface of the lung was seen to be interrupted in many places by the invasion of what was obviously a malignant growth. In spite of this, as the tumour was so discrete, lobectomy was advised. This was performed by Mr. Romanis on March 21. Apart from a temporary empyema, which was drained and soon resolved, the patient made an excellent recovery, and six weeks later was well, gaining strength and putting on weight. He went away to a convalescent home, and six months later returned with the left side of the chest completely filled by malignant growth, apparently arising from the mediastinal glands.

Case II

A man aged 48 years was admitted to the London Chest Hospital complaining of pain between the scapulae. He had been quite well until two months before, when he was seized with an acute pain in the chest. The pain was increased by inspiration. This was followed by cough and some blood-stained sputum.

Physical examination was negative, except for some impairment of the percussion note in the left interscapular region. The Wassermann reaction was negative. The skiagram revealed a lobulated mass the size of a grapefruit, arising from the left hilar region. A true lateral skiagram showed a single spherical mass lying posteriorly. The bronchoscopic examination revealed some pressure coming from without, partially occluding the left main bronchus. An artificial pneumothorax was induced, and a thoracoscope was introduced into the fifth space anteriorly. The lung could be seen to be collapsed and free; the mass, reddish yellow in colour, was lying in the substance of the lung and infiltrating along under the visceral pleura. The condition was obviously malignant. In view of this no operation was considered, and the patient died six months after leaving hospital.

Case III

A woman aged 30, seen privately in March, 1938, complained of pain in the mid-sternal region. Eight weeks previously she had had pleurisy with some fluid on the left side. She was kept in bed for fourteen days, then went to her home town for convalescence. While there she consulted her own family doctor, who, because of the history of pleurisy, had the chest x-rayed. The radiograph revealed a mass on the right side, perfectly rounded in outline, apparently arising from the mediastinum opposite the region of the shadow of the aortic knuckle (Plate, Fig. 1). The true lateral skiagram showed the tumour to be situated posteriorly. An interesting feature in the history was that she had been hit by a tennis ball in the mid-sternal region four years before, and ever since she had experienced pain on and off in that region.

On admission to the London Chest Hospital a diagnostic pneumothorax was induced on the right side and the lung collapsed away from the tumour, leaving it free, unchanged

in position, and unaltered in shape. A thoracoscope was inserted in the fourth space, in the mid-axillary line, and a bluish-purple tumour could be seen, with fine veins on its surface arising in the posterior mediastinum from behind the great vessels and extending almost up to the arch of the subclavian artery and completely independent of the lung. A painting was made by Mr. Shiells (Plate, Fig. 2).

Four days later the patient was operated on by Mr. Holmes Sellors, and so far as was possible the tumour was removed. It was filled with a chocolate-coloured thick creamy substance. This was sucked out and finally mopped dry with gauze. The portion of the wall of the tumour under the great vessels had to be left behind; it was wiped clean and swabbed with formalin. The patient made an uninterrupted recovery.

The report on the tumour was as follows: "The cyst wall consists in great part of vascular fibrous tissue with a striking amount of lymphoid tissue disposed mainly around the vessels. In some parts large thin-walled blood spaces are seen and haemorrhage has occurred. Other components of the cyst wall are fat, bundles of muscle fibres, ciliated columnar epithelium, and acinous glands. No ectodermal elements have been recognized, and no cartilage or bone." The blow from the tennis ball had possibly caused a haemorrhage into the teratoma.

Case IV

A man aged 33 complained of pain in the right side of the chest. Sixteen months previously he had had pain in the region of the dorsal spine radiating to the right costal margin anteriorly. For this condition he was admitted into a hospital in the North, where, after complete investigation, his appendix was removed; the pain, however, still persisted. Because of this he was again examined, and a skiagram of his chest revealed a mass in the right lung. He was admitted into the London Chest Hospital.

Physical examination was negative, except for some change in the percussion note at the right base posteriorly. The Wassermann reaction and the Casoni test were negative. The skiagram revealed a single spherical mass with smooth, sharply defined borders the size of an orange, situated in the right lower lung field (Plate, Fig. 3). A true lateral skiagram showed the mass to be lying close to the vertebral column (Plate, Fig. 4). Bronchoscopic examination was negative. An artificial pneumothorax was induced; the lung appeared to collapse away from the tumour, suggesting an innocent condition. A thoracoscope was introduced into the fifth space in the mid-axillary line. The mass was seen to be reddish yellow in colour, arising from the chest wall close to the vertebral column. It appeared to have a well-defined capsule. The lung was adherent to the growth at one point only, but it was infiltrated with multiple yellow sago-like nodules. Adjacent to the tumour, on the chest wall, were three secondary masses the size of a pea.

A section of the tumour was taken by means of forceps introduced through a second cannula; no undue bleeding was caused by this procedure. The section was reported by Drs. Gloyne and Page as a mixed-cell sarcoma. ? malignant change in a neurofibroma. In view of these findings a radical operation was regarded as impossible, and the patient was referred for deep x-ray therapy.

A recent necropsy provides another illustration of the potentialities of the method.

A woman was admitted to another hospital with a massive pleural effusion. The spleen was enlarged and a mass could be felt in the epigastrium. All the usual tests were made, but without result, and the differential diagnosis was malignant growth or lymphadenoma. An exploratory laparotomy had been advocated by two or three physicians as a diagnostic measure. Before this was done, however, the patient died. The post-mortem examination revealed a huge malignant mass behind the stomach, large secondary growths in the spleen, and metastases in many other parts; but, what is of interest in connexion with this communication, there were a number of raised white nodules the size of half a pea-nut on the

parietal pleura. It would have been a simple matter to replace the fluid by air through the thoracoscopic cannula, to insert the telescope, see the nodules, and remove a portion for section, whereas the proposed alternative would have been highly dangerous.

As regards technique, one of us (F. G. C.) uses a single-cannula method with a direct-vision telescope. Through this single cannula all instruments can be inserted, including the biting forceps and a diathermy knob for the arrest of haemorrhage, if any. The other employs the two-cannula technique when removing a piece of the growth for section.

Conclusion

The cynics have suggested, occasionally with some truth, that modern methods of investigation are more distressing and dangerous to the patient than the disease itself; but this criticism cannot seriously be advanced in the case of an exploratory thoracoscopy: for in skilled hands the patient should feel nothing more than the first hypodermic injection of the local anaesthetic, and it is clear that this investigation, as illustrated by Cases II and IV, may save the patient an unnecessary thoracotomy. If a pleural effusion is present, then the thoracoscopy can be carried out at the same time as the aspiration provided the paracentesis is accomplished through a thoracoscopic cannula, a procedure which gives more efficient evacuation of the fluid than an ordinary needle, with no more discomfort.

With ordinary aseptic precautions an exploratory thoracoscopy should be without risk to the patient. This has been our experience with a large number of cases.

CONGENITAL ATRESIA OF THE OESOPHAGUS

BY

J. W. D. BULL, M.B., M.R.C.P.
Medical Registrar, St. George's Hospital

(WITH SPECIAL PLATE)

The following case is recorded not on account of its rarity but because the condition has been so seldom mentioned in the English literature.

Case History

The patient was a female child born on August 23, 1937, of healthy parents. The mother had had three pregnancies: boy, who died at the age of 3 of pneumonia; a miscarriage; and the patient. Delivery in the present case, in the maternity ward of St. George's Hospital, was spontaneous and normal. Excessive liquor amnii was noted. There was some difficulty in reviving the baby, as she seemed choked with mucus. The excess of mucus continued, but nothing alarming was observed until the second day, when the mother's milk had come in. On being put to the breast the baby sucked easily, but in a few minutes choked, and turned blue in the face. The nurse rescued it, and sucked out the milk and mucus from its mouth. The same result was obtained at the next feed. Mucus in the mouth increased in quantity, and, apart from the attempted feeding, the child had attacks of cyanosis, which were relieved by clearing the throat.

On the second evening Dr. T. F. McNair Scott examined the child. It was lying in the cot, breathing with some difficulty and through a great deal of moist mucus in the mouth and nose. It was normally developed and nourished, but moderately dehydrated. The skin was clear. No glands were palpable. Examination of the head revealed no craniotabes. The anterior fontanelle measured about $1\frac{1}{2}$ by $1\frac{1}{2}$ inches, being depressed, and the posterior fontanelle one finger-tip.

The eyes, mouth, nose, ears, neck, and heart were normal. There was no impairment of percussion note anywhere in the lungs. Breath sounds were transmitted mainly to the interscapular region. Nothing abnormal was found in the abdomen. Respiratory sounds were clearly transmitted to the stomach region. The genitalia were those of a normal immature female and the limbs were normal. Meconium was being passed.

From the history of excessive mucus and inability to take food without choking, a diagnosis of congenital absence of the oesophagus was made.

INVESTIGATIONS

1. *Radiological.*—On examining the baby under the screen it was immediately noticeable that the stomach contained no air. After the child had sucked the bottle containing milk and a barium salt, some air did appear in the stomach. The opaque meal was seen to enter, and to distend a blind point of the oesophagus which ended at the level of the second thoracic vertebra. The baby vomited soon after, and became very choked up. A radiograph confirmed the condition (Plate, Fig. 1). In addition a hemivertebra was present between the fifth and seventh thoracic, and the sixth right rib was absent.

2. *Examination of meconium* by staining a smear of it with gentian-violet and decolorizing with acid alcohol—Farber's test (1933)—revealed the presence of squamous epithelial (amniotic) cells as in normal meconium. This indicated that there must be a communication between the mouth and the intestine. Since the proximal part of the oesophagus ended in a blind pouch there must have been a communication between the trachea and the stomach.

COURSE

In view of the above findings it was decided that no operative intervention was indicated. All feeding by mouth was stopped, and the baby was kept hydrated by the introduction of from 60 to 120 c.cm. of 5 per cent. glucose and saline intraperitoneally twice daily. The cot was kept at an angle of about 30 degrees, the head being down. Mucus continued to be quite profuse, and the baby had several attacks of cyanosis. With the aid of suction, and 1/200 grain of atropine when considered necessary, this was overcome. The baby remained comfortable, and slept most of the time.

The physical signs did not change much from those originally described until the day before death. The lungs remained resonant to percussion, but adventitious sounds developed, mainly rhonchi and coarse rales. On that day, following the intraperitoneal injection, quite profuse bleeding occurred from the puncture wound. Local pressure and thromboplastin were used, but the ooze continued. About thirty-six hours afterwards, with cessation of bleeding, the baby died. The blood taken after death was sterile. It was noted, however, that clotting did not occur.

Haemorrhage occurring in a newborn infant associated with delayed or absent clotting suggested a diagnosis of haemorrhagic disease of the newborn. The unusual feature here was that the onset of the bleeding was delayed to the eighth day in the absence of a septicaemia.

Before performing the necropsy it was decided to inject lipiodol into the trachea to see if the suspected tracheo-oesophageal fistula could be demonstrated. This was seen on the screen, and the lower portion of the oesophagus was shown to be leaving the trachea about five millimetres above the bifurcation. The lipiodol filled the bronchial tree and passed to the lower end of the oesophagus (Plate, Fig. 2). It was prevented from entering the stomach by an air-lock, as was afterwards discovered at necropsy.

Necropsy

The body was that of a somewhat wasted child. There were numerous puncture marks on the abdominal wall. The congenital atresia of the oesophagus was confirmed, as was also the tracheo-oesophageal fistula (Plate, Fig. 3—St. George's Hospital Pathological Museum). A window has been cut in the anterior border of the trachea to show the fistula. There

was no fibrous communication between the two portions of the oesophagus. The stomach contained no food, only meconium. The rest of the gut was normal, as were the biliary system, liver, and spleen. The heart and great vessels were also normal, but the ductus arteriosus was still patent. The suprarenals were normal in size, shape, and position. The right kidney and ureter were normal. The left kidney was extremely atrophic, and the pelvis was very dilated and was as large as the kidney itself. The ureter, which entered the bladder, was very short, and as a result the left kidney was within the pelvis minor. The bladder and urethra were normal. The genital system was also abnormal on the left side. The left cornu of the uterus had not developed at all, and the left round ligament joined the right cornu at its cervical end. The medial end of the left Fallopian tube terminated blindly at some distance from the uterus. The left ovary appeared normal. The drawing here reproduced shows the condition

diagrammatically, the bladder being omitted for the sake of simplicity. No other abnormalities were found.

Cases in the Literature

The first published case of this condition was observed by Thomas Gibson (1703), a Fellow of the College of Physicians, in 1679, and it is noteworthy that his clinical description was faultless. He afterwards performed a necropsy, on which the diagnosis was made. Since then, however, the condition has received scant attention in the English literature, and it has been left to the American schools particularly, and to some extent the European schools, to draw attention to it.

Plass (1919) collected 136 cases. He showed that about 30 per cent. had other congenital abnormalities. Rosenthal and Himmelstein (1932) noted 255 cases in the literature, and 204 of these had tracheo-oesophageal fistulae. Recently at least ten cases have been reported annually. The various types of abnormality have been classified by McClellan and Elterich (1934). They describe twelve different types, which are clearly understood when one considers the development of the oesophagus and trachea. Keith and Spicer (1907) described the embryology, and Keith (1910) illustrated it by cases in a later publication. They state that in the 3.2 mm. embryo (third week) the floor of the anterior part of the primitive oesophagus becomes evaginated and forms the trachea. In the 12.5 mm. embryo (fifth week) the tracheo-oesophageal septum has completely formed.

The symptomatology as described in the case above is quite typical. Few live more than a week, and none has lived more than a month. Death is nearly always due to bronchopneumonia.

Treatment

Gastrostomies have been performed repeatedly; but, unless the cardiac end of the stomach is tied, the food flows backwards up the oesophagus into the trachea, except in the very few cases where there is no tracheo-oesophageal fistula. It has been the hope of some surgeons to keep the patients alive long enough to perform an intrathoracic plastic operation at a later date. This seems a forlorn hope, and it is questionable whether it would be justified even if successful, for so many cases are associated with multiple congenital lesions.

Summary

1. A report of a case of congenital atresia of the oesophagus with tracheo-oesophageal fistula is given.
2. The indications are that the anomaly occurs much more often than is generally believed.
3. The anomaly is nearly always associated with other congenital lesions.
4. It produces a quite characteristic syndrome, which if kept in mind makes a clinical diagnosis relatively simple.
5. Auxiliary methods of diagnosis are mentioned.
6. Death has occurred within four weeks in every recorded case.

I should like to express my thanks to Dr. T. F. McNair Scott, recently paediatrician to St. George's Hospital, for allowing me to record this case.

THE BACTERIOSTATIC EFFECTS OF SULPHONAMIDE-P, SOLUSEPTASINE, AND M & B 693

BY

B. G. MAEGRAITH, M.B., B.Sc., D.Phil.

AND

R. L. VOLLUM, D.Phil.

(From the Sir William Dunn School of Pathology, Oxford)

The bacteriostatic properties of these three drugs on *Streptococcus viridans* and *Staphylococcus aureus* were examined by the slide method of Wright, modified by Fleming (1924, 1938). A different technique, described below, was necessary in the cases of *Neisseria gonorrhoeae* and *N. meningitidis*, as these organisms did not show sufficiently differentiated colonies for counting. The drugs were dissolved in saline and kept made up in dilutions of 1 in 1,000, sterilized by heating to 60° C. for one-half to one hour.

Streptococcus viridans and *Staphylococcus aureus*

TECHNIQUE

The tests were set up in the following manner. First a suspension of a fresh culture of the organism in sterile saline was prepared and matched to correspond in density with Brown's No. 1 tube. Human blood was then withdrawn and defibrinated by shaking with glass beads. Half

of the blood was separated and forced five to seven times through cotton-wool to reduce the number of leucocytes present. In this way the white cell count was lowered to 500 to 1,000 per c.mm. and most of the polymorphs were removed. Blood so treated is referred to below as "deleucocytized." Defibrinated blood was found to be slightly deleucocytized, the white cell count after defibrination falling from about 7,000 to 5,000 per c.mm., but many polymorphonuclear cells were still present.

Mixtures were then made of one volume of suspension of the organisms to three volumes of defibrinated and of deleucocytized blood. Equal volumes of the blood-organism mixtures and the dilution of the antiseptic were then mixed and slides set up as described by Fleming. Three dilutions of each chemical substance were employed, and the final dilutions in the compartments of the slides were 1 in 2,000, 1 in 20,000, and 1 in 60,000. Prepared slides were incubated at 37° C. in moist conditions for twenty-four hours, and after incubation colonies were counted under the low power of a microscope.

RESULTS

Streptococcus viridans—Three strains isolated from patients' throats were examined, and the results in all three examinations showed that the drugs affected the growth of the organisms, but only in the presence of white blood corpuscles, including polymorphs. A typical result of a count of *Str. viridans* is shown in Table I.

TABLE I.—Effect of Drugs on *Str. viridans*

Drug	Number of Colonies in Dilutions of—			Control
	1 2,000	1/20,000	1/60,000	
M & B 693:				
a	16	20	20	900 +
b	Uncountable in all dilutions			++ +
Sulphonamide-P:				
a	30	600	900	900 +
b	Uncountable in all dilutions			++ +
Soluseptasine:				
a	20	800	800	900 +
b	Uncountable in all dilutions			

a mixed with defibrinated blood. b mixed with deleucocytized blood.
— sign after a number indicates the presence of very small colonies not counted in the figure quoted

Similar results were obtained for the other strains of *Str. viridans*. In the presence of defibrinated blood containing normal numbers of white cells it will be seen that M & B 693 is a very efficient bacteriostatic agent, even at a dilution of 1 in 60,000, whereas the other two drugs are efficient at a dilution not greater than 1 in 2,000. In deleucocytized blood none of the drugs has much bacteriostatic effect, although the colonies appear much smaller in the high concentrations than in the controls, which contained no drugs.

Staphylococcus aureus.—None of the drugs appeared to have the slightest effect on the growth of this organism. Two strains of *staphylococcus*, one freshly isolated from a boil, were examined, and in both cases the growth after twenty-four hours was confluent and general in all slides.

Neisseria gonorrhoeae and *N. meningitidis*

TECHNIQUE

These organisms were examined by the slide method, but this was abandoned after a few experiments, as colony formation was poor, making counting very difficult. The following method was then devised. Mixtures of one volume of suspensions of fresh cultures of the organisms and three volumes of defibrinated and deleucocytized blood

respectively were prepared as before. Fifteen drops of these mixtures were then measured into sterile dwarf test-tubes, and equal volumes of the various dilutions of the drugs were added. The final dilutions of the drugs were the same as in the slide technique. The mixtures were shaken and incubated at 37° C. for twenty-four hours under moist conditions. After incubation samples of the contents of the tubes were plated out on blood agar and the plates were incubated for a further twenty-four hours in a moist chamber. The number of colonies on each plate was then counted, and in this way an estimate of the bacteriostatic effects of the dilutions of the drugs was obtained. Table II illustrates a typical result with a stock culture of *N. gonorrhoeae*.

TABLE II.—Effect of Drugs on *N. gonorrhoeae*

Drug	Number of Colonies in Dilutions of—			Control
	1/2,000	1/20,000	1/60,000	
M & B 693 :				
a	0	0	10	77
b	73	80	32	26+
Sulphonamide-P :				
a	6	17	5	77
b	7	9	29	26+
Soluseptasine :				
a	0	2	11	77
b	1	3	3	26+

Here again two of the drugs acted much better in the presence of a full complement of leucocytes. Thus M & B 693 was bacteriostatic at a dilution of 1 in 60,000 in the presence of defibrinated blood, whereas when mixed with de-leucocytized blood it did not appear to be bacteriostatic at a dilution of 1 in 2,000. Sulphonamide-P (sulphanilamide) was bacteriostatic at 1 in 60,000 in the presence of defibrinated blood, but was not active at this dilution when mixed with de-leucocytized blood. This activity of sulphonamide-P is in agreement with the clinical findings of Cokkinis and McElligott (1938). Soluseptasine was active at all dilutions in both defibrinated and de-leucocytized blood. In this case it is possible that some difference in activity might manifest itself at higher dilutions of the drug.

Neisseria meningitidis

Preliminary experiments with a number of different strains of *N. meningitidis* indicated that soluseptasine was not as effective an agent against this organism as was M & B 693. Thus, in mixtures containing normal cerebrospinal fluid, a suspension of an organism grown from a fatal case in a recent epidemic, and various dilutions of the drugs, soluseptasine was found to be bacteriostatic at a dilution of 1 in 1,000 and not at 1 in 10,000, whereas M & B 693 was effective at a dilution as high as 1 in 50,000, even in the absence of blood.

When the organisms were examined by the method described above these results were confirmed, as may be seen in Table III.

The results shown in Table III indicate that in high dilutions the drugs act better in the presence of leucocytes—that is, in defibrinated blood. In lower dilutions sulphonamide-P appears to work slightly better in the absence of the leucocytes. This, however, was not a constant finding.

Of the three drugs M & B 693 appears to inhibit growth slightly more successfully than the other two in all dilutions, and with or without leucocytes. Sulphonamide-P is also effective in high dilution even in the absence of

leucocytes. It should be noted here that our results with this drug are better than those obtained by other authors

TABLE III.—Effect of Drugs on *N. meningitidis*

Drug	Number of Colonies in Dilutions of—			Control
	1/2,000	1/20,000	1/60,000	
M & B 693 :				
a	13	23	11	Confluent
b	0	20 (inf.)	80+	"
Sulphonamide-P :				
a	170	134	54	"
b	23	60	105	"
Soluseptasine :				
a	77	74	300+	"
b	44	700+	confluent	"

" Inf." means that the plate was slightly infected.

(Branham, 1937; Neter, 1938). Soluseptasine has the least effect on the growth of the organisms, although it is active at a dilution of 1 in 20,000 in defibrinated blood.

Summary

The bacteriostatic effects of sulphonamide-P, soluseptasine, and M & B 693 have been examined.

All three drugs inhibit the growth of *Str. viridans* at a dilution of 1 in 2,000 in the presence of defibrinated human blood, M & B 693 doing so at a dilution as high as 1 in 10,000. None of these drugs is effective in the absence of leucocytes.

None of the drugs exhibits any bacteriostatic effect on *Staph. aureus*.

The growth of *N. gonorrhoeae* is retarded by all three drugs in the presence of leucocytes. In de-leucocytized blood soluseptasine still exerts a strong bacteriostatic effect on the organism.

All the drugs are effective against *N. meningitidis* in the presence of corpuscles—in the case of M & B 693 at a dilution of 1 in 60,000. That drug is active at a dilution of 1 in 60,000 even in the absence of blood.

The dependence of these drugs on the presence of leucocytes is in agreement with the findings of Fleming (1938).

From the evidence set forth above it appears that M & B 693 may prove the most useful therapeutic agent in cerebrospinal fever and in conditions arising from infection with *Str. viridans*. Soluseptasine seems the most satisfactory for dealing with *N. gonorrhoeae*.

The drugs used in the above experiments were supplied by Burroughs Wellcome (sulphonamide-P), Dr. Ewins of May and Baker (M & B 693), and Dr. F. G. Hobson, Radcliffe Infirmary (soluseptasine). We wish to express our thanks for these gifts.

C. D. De Langen, J. C. Boswijk, and C. L. C. van Nieuwenhuizen (*Nederl. Tijdschr. Geneesk.*, 82, 4970) record an outbreak of ten cases of pellagra in female patients in a mental hospital. Six had refused food, three had already suffered from gastro-intestinal disturbances, and one was under treatment by cardiazol. Nine of the patients were treated with nicotinic acid in doses not exceeding 200 mg. daily; all recovered without any severe toxic symptoms. One patient who was not so treated died.

SPONTANEOUS HYPOGLYCAEMIA

WITH REPORT OF A CASE

BY

J. A. PRICE, M.D., M.R.C.P.

Assistant Physician, Royal Infirmary, Bradford

AND

A. B. RAPER, B.Sc., M.D., M.R.C.P.

*Resident Medical Officer and Assistant Pathologist,
Royal Infirmary, Bradford*

The syndrome of spontaneous hypoglycaemia is one that has received comparatively little attention in English medical literature, although numerous cases have been reported in America, Australia, and Europe; nor has it found a place in the standard textbooks of medicine in this country. Wauchope in her critical review (1933) quotes only one English case, that of Moore and his colleagues (1931), in which the syndrome resulted from amylaceous dyspepsia. Full descriptions of the clinical and pathological features of this condition have been given by several American authors, notably by Gammon and Tenery (1931) and Seale Harris (1933), who have also reviewed the literature; while in the last seven years eight cases have been reported in this country.

Review of English Literature

Ramsbottom and Eastwood (1932) recorded their experience with a woman aged 44 whose condition had been diagnosed by Dr. Eurich at the Bradford Royal Infirmary in 1930. This was a somewhat unusual case, in that Argyll Robertson pupils and extensor plantar responses were present in the intervals between attacks without any evidence of syphilis. At laparotomy no pancreatic abnormality was found, but an infected gall-bladder and appendix were removed, after which the patient improved temporarily, only to relapse in spite of a daily dose of 1 lb. of glucose. Barnard (1932) described a case in a woman aged 40 who died in hypoglycaemic coma, and in whom an adenoma of the islets of the pancreas was found; treatment with glucose had been tried with temporary relief, but glucose was ineffective in the final stages. Cairns and Tanner (1933) reported the case of a woman aged 52 who, after two years' history of recurrent "giddy" attacks, passed into hypoglycaemic coma. The blood sugar was found to be 41 mg. per 100 c.cm., and the patient died in spite of intravenous glucose injections, adrenaline, and pituitrin. Necropsy revealed an adenoma of the pancreas.

The case of a woman aged 41 who had previously received insulin treatment for diabetes was recorded by Griffiths and de Wesselow (1933). The sugar-tolerance curve of this patient was of the "lag" type with a final hypoglycaemia, and the clinical course and laboratory findings were noticeably erratic—features which were observed in some of Wilder's (1927) cases, and considered by Howland (1929) to suggest a malignant rather than a benign growth. There was no clear evidence of liver dysfunction, though on one occasion the adrenaline test gave negative results. Moore *et al.* (1934) recorded a case which they considered to be due to subacute parenchymatous hepatitis; they also gave the ultimate history of a previously reported case (1931), and mentioned having seen another case, in a man of 28, of "apparently true hyperinsulinism." One of the patients referred to by Jones (1935) as presenting mental symptoms due to hypoglycaemia was a man of 31, and the details given leave

little doubt that he suffered from spontaneous hypoglycaemia of pancreatic origin.

We present below the records of another example of spontaneous hypoglycaemia. It is probable that the condition is not so rare as is generally supposed, and that as its features are more widely known it may be increasingly recognized, and experience with a larger number of cases may enable a truer assessment to be made of the possibilities of treatment.

Case Report

A man aged 41, a painter, was referred to one of us as a "peculiar epileptic." For the past eleven years he had suffered from attacks of dizziness and unsteadiness of gait. At first these occurred only once or twice a year, but they had increased in frequency latterly, so that in the past year he had had one or two a week, and in the week before his admission to the Bradford Royal Infirmary on February 27, 1938, they were of daily occurrence: his doctor described him as "a nuisance to the neighbourhood" by reason of his malady. The patient had previously been healthy except for an attack of influenza in 1918; he had begun to put on weight at about the age of 30, when symptoms first appeared, but his weight had remained stationary at about 13 stone for the last few years. His parents, four sisters, and one brother are alive and well, and do not suffer from any symptoms that might be ascribed to hypoglycaemia or diabetes.

NATURE OF THE ATTACKS

Attacks are almost always heralded by a sensation of tingling, which is felt first in the lips when he is eating, in the right hand when he is engaged in manual work, and in the feet when he is walking. If an attack begins while he is reading the newspaper the first sign would be that the words "run together." After these prodromal symptoms the commonest form taken by the attack is a sensation described as "muzziness of the head" accompanied by lack of concentration, slight blurring of vision, and some confusion. Occasionally hallucinations occur, and as a result of these "dreams" the patient exhibits unusual though never violent conduct. During an attack his speech is slow and drawing and the attention wanders, there has never been any sphincter disturbance, abnormal sleep, headache, convulsion, or loss of consciousness. On two occasions, the first many years ago and the second fourteen months ago, the patient found that the right arm and leg became useless during an attack; the face has never been affected. The paresis lasted a few hours on each occasion and disappeared gradually.

More severe attacks have occurred, usually when walking home from work. Tingling in the feet is followed by a drunken feeling and unsteadiness of gait, so that he leans for support on a wall or railing. The attack develops slowly enough for him to board a bus and reach his home; but here he collapses in a chair, feeling cold, faint, and confused, and often sweating. An attack may last for half an hour to one and a half hours, and always develops and passes off slowly. Most frequently attacks occur towards the end of the day's work, but they have also occurred before mealtimes and sometimes during a meal. The patient does not experience hunger during an attack, but he knows that if he takes food he can prevent a severe one developing, and he has formed the habit of having a mid-morning lunch at work for this reason.

EXAMINATION

The patient was a moderately obese subject weighing 13 stone, with an old-standing strabismus and myopia. The fat was of normal distribution, there was no unusual pigmentation of the skin, the hair was normal, as was the development of the sexual organs. Examination of the nervous system revealed no abnormal signs, while the only abnormality found in a general examination was a blood pressure of 170/100 mm. Hg. The urine and the cerebrospinal fluid were normal, and the Wassermann reaction was negative.

From a description of the attacks hypoglycaemia was suspected, and this view was confirmed on reducing the diet the next day. Whilst having his tea on this day the patient developed a typical attack in which the blood sugar was found to be 40 mg. per 100 c.cm. The sugar-tolerance curve after 50 grammes of glucose gave the following results:

Time	Before Sugar	30 mins.	60 mins.	90 mins.	120 mins.
Blood sugar (mg. per 100 c.cm.)	25	40	92	75	66

There was no glycosuria during the test, but sugar was found on one occasion in the early morning urine..

Further investigations to determine the aetiology of the hypoglycaemia were undertaken; the stools contained no undigested starch, and no diarrhoea was present. Pituitary function appeared to be normal, there was no radiological abnormality of the pituitary fossa, and the fields of vision were normal. The basal metabolic rate gave a value of -3 per cent. A test meal showed a rapid emptying time and a normal acid curve. There was no evidence of diminished laevulose tolerance. After a dose of 40 grammes of laevulose the following figures were obtained:

Time	Before Laevulose	30 mins.	60 mins.	90 mins.	120 mins.
Blood sugar (mg per 100 c.cm.)	31	31	28	24	20

Mobilization of sugar occurred normally after the subcutaneous injection of 10 minims of adrenaline:

Time	Before Adrenaline	10 mins.	20 mins.	30 mins.	40 mins.	50 mins.	60 mins.
Blood sugar (mg. per 100 c.cm.)	66	55	96	130	145	146	186

Discussion

Various authors have discussed the pathogenesis of hypoglycaemia, and its possible causes have been summarized by Wauchope (1933) as follows:

- 1. *Excess of Insulin.*—Therapeutic injections. Tumours and hyperplasia of the pancreas. Functional hyperinsulinism (idiopathic hypoglycaemia).
- 2. *Lack of Opposing Secretions.*—Disease of the suprarenal glands. Pituitary tumours: posterior lobe, anterior lobe (acromegaly). Myxoedema.
- 3. *Lack of Glycogen.*—Destruction of reservoirs: disease of the liver; wasting of muscles. Abnormal excretion of sugar: renal diabetes; lactation. Active depletion of stores: muscular exercise. Failure to replenish stores: starvation.
- 4. *Interference with Regulating Centre.*—Nervous disease affecting the pons. Overaction of the vagus.

In the present case no evidence had been obtained of disorder of the adrenal, pituitary, or thyroid glands; liver and gastro-intestinal functions were normal, and there was no renal diabetes. It seemed, therefore, that the cause must be sought in the pancreas.

From a study of the previously reported cases it appears that there is as yet no satisfactory criterion whereby the varieties of pancreatic hypoglycaemia may be differentiated. In the cases reported up to 1931 (Gammon and Tenery, 1931) the average duration of symptoms when a patient was first seen was two and a half years in the tumour group and four years in the non-tumour group, the longest periods being seven years and thirteen years respectively in the two groups. The erratic course of tumour cases has been stressed, but this has not been apparent in all such cases, although it might seem feasible that an adenoma or carcinoma, presumably exempt from

nervous control, should show a fluctuation in its functional activity dependent upon variations in its rate of growth. From those cases in which the adrenaline response has been observed there is some reason to suppose that it is more often negative in tumour cases, but the difficulties in interpreting this test are pointed out by Cammidge and Poulton (1933). The latter incline to the view that lack of response to adrenaline cannot be due to pancreatic hyperfunction, and criticize Wilder's explanation that the adrenaline must be swamped by excess of insulin, on the grounds that a balance must always exist, and that this must always be susceptible to alteration on the addition of more adrenaline. If, however, Wilder's view is correct, a negative adrenaline response might indicate exhaustion of the adrenaline-supplying mechanism, or possibly a diminution in sensitivity to adrenaline. In either case it would be expected to denote the severity of the disease rather than its pathological basis, and this is borne out by the fact that adrenaline often fails to relieve severe hypoglycaemia from any cause. The state of affairs in the pancreas is not always capable of diagnosis even at laparotomy, for small adenomata may be missed (Ziskind and Bayley, 1937).

On the evidence available, therefore, we concluded that a definite pathological diagnosis could not be made, and that there was as yet no indication for exploratory laparotomy.

Treatment

Medical treatment is of course palliative. Its aim is to keep the blood sugar from falling too low, and also from fluctuating too violently. To assess the value of the different methods available we first observed the blood-sugar variations in the patient on an ordinary ward dietary, and the results are shown in Fig. 1.

FIG. 1.

It has been suggested (Harris, 1933) that rational therapy should consist in measures which avoid stimulation of pancreatic activity. Accordingly the patient was given a diet consisting of carbohydrates 100 grammes, protein 70 grammes, and fat 160 grammes, and on the third day of this regimen the blood-sugar variations were again followed (Fig. 1). On the first day of this diet the patient felt worse than at any time since admission, but he had improved considerably by the fifth day. On the sixth day, however, he had a severe attack in which there was twitching of both legs but no other abnormal nervous signs. During all this period he complained of being "terribly tired." A diet of carbohydrates 500 grammes,

protein 70 grammes, and fat 70 grammes was then given, divided into seven meals. Subjectively his condition on this diet was better than with the previous one, though he still had "pins-and-needles" in the lips. The diet was then supplemented by injections of 10 minims of adrenaline at 5.30 p.m., 10.30 p.m., and 10.30 a.m., and the results of this appear in Fig. 1. A week later he had had no tingling of the lips for a few days, and stated that he would be quite satisfied if his present condition remained unchanged. He was discharged on the high carbohydrate diet, and ephedrine, $\frac{1}{2}$ grain thrice daily by mouth, was substituted for the injections of adrenaline.

On July 7, 1938, the patient was readmitted. Subsequent to his discharge he had had no attacks for six weeks, but had had a total of four attacks in the whole period of fifteen weeks. His weight had been stationary, and his general health and temper had improved: the blood pressure remained at 170/100 mm. Hg. The patient stated that on each occasion an attack had been the result of a delayed meal, and that with greater care he could have prevented them. The ephedrine was stopped temporarily and the daily blood-sugar variations again recorded while the patient was taking the 500-gramme carbohydrate diet. The results given below indicate that a higher blood-sugar level had now been attained, and it was also noted that prodromal symptoms of hypoglycaemia occurred at a higher level of blood sugar than previously, suggesting that during the previous weeks the nervous system had become accustomed to more normal conditions.

FIG. 2.

The duration of the response to ephedrine was next determined, and as it was found to cause a rise of blood sugar, beginning about three hours after administration and lasting two hours, the patient was discharged on July 15, 1938, with instructions to take ephedrine tablets four times daily at approximately 8 a.m., noon, 5 p.m., and bedtime. His diet was rearranged to contain 650 grammes of carbohydrate, divided into ten meals.

In view of the good response to medical treatment exploratory laparotomy was further postponed.

Commentary

One of the most striking features of this case is the extraordinarily low blood-sugar readings obtained in the absence of severe hypoglycaemic symptoms. Figures in the region of 30 mg. per 100 c.cm. were recorded several times, and even when the blood sugar reached the level of 16 mg. on one occasion and 20 mg. on another the patient was not in coma. So far as we are aware this has not been recorded before. (The blood sugar was estimated by a modification of the method of Calvert (1924) using the Zeiss photometer, and the technique was checked by estimation of glucose solutions of known strength.)

It will be noted that the point at which tingling or weakness first appeared was often determined by use of the part—for example, tingling of the legs when walking

and of the lips when eating—suggesting that some local product of muscular metabolism was the determining factor. Generalized muscular weakness of sudden onset in familial periodic paralysis is known to be associated with a fall in blood potassium, and an attack in this condition may be brought on by administration of glucose or insulin, or both together (Aitken and Allott *et al.*, 1937). In chronic hypoglycaemia the same biochemical abnormalities may occur, and it is possible that in the case here recorded the extra demand of neuromuscular activity interfered with the already disturbed potassium balance and produced the symptoms noted. The fall in the blood potassium was confirmed in the present case, for during a hypoglycaemic attack in which the blood sugar was 30 mg. per 100 c.cm. and weakness of hand-grip was evident the serum potassium fell from its normal of 21.4 mg. to 15.9 mg. per 100 c.cm. Unfortunately the effects of administration of potassium salts have not been observed.

Another unusual point concerns the time of onset of symptoms. Most cases show symptoms when fasting, and especially just before meals, but here it was repeatedly observed that the attacks began just after the patient had started to eat. This might be merely another example of the local effects of exercise mentioned above, the blood sugar being already low, or it might be due to an actual lowering of the blood sugar, presumably by means of a conditioned reflex. The same effect was noted by Howland (1929). Personal experiments on a normal subject, however, lent no support to the hypothesis that a reflex lowering of the blood sugar occurred when a meal was contemplated. Moreover, Howland's case was one of carcinoma, which could not be expected to be susceptible to nervous impulses.

Lastly, it may be pointed out that hemiparesis is a recognized though uncommon feature of hypoglycaemia, and it is important to recall the fact that this rather alarming occurrence may be a transient manifestation of the condition. We have come across similar attacks in a diabetic boy aged 11 years who was receiving protamine insulin, and in an adult aged 30 under similar conditions.

Summary

1. References to spontaneous hypoglycaemia in the English literature are reviewed.
2. The records of an additional case are presented and the difficulties of diagnosis and treatment discussed.
3. Certain unusual features in the symptomatology are commented upon.

Clinical Memoranda

Treatment of Delayed Union of the - Carpal Scaphoid

(WITH SPECIAL PLATE)

In the *British Medical Journal* of December 4, 1937, Mr. R. Salisbury Woods described a case of union of the carpal scaphoid after six weeks' delay in treatment. The excellent result obtained in his case induced me to trace for review a patient treated in a similar conservative manner about a year previously. In this case the period between the accident and the institution of efficient treatment had been much longer—nearly three years—and the period of treatment had been correspondingly extended. The result, however, proved very satisfactory, and the publication of such a case may encourage others to consider conservative measures when treating this most troublesome injury.

CASE HISTORY

In April, 1936, a man aged 30 was referred to me because of increasing pain and disability of the right wrist. The history was that three years previously he had skidded on a motor-bicycle and fallen on his right side with his hand still grasping the handle-bar. The right wrist was damaged and a diagnosis of "sprained wrist" was made. Treatment was limited to the usual home hydrotherapy efforts.

After six months of continued pain he sought advice elsewhere, and a radiograph was taken which showed a transverse fracture of the carpal scaphoid. He was told that the fracture would probably unite. He managed to carry on at his work as a metal turner, but pain persisted. When seen by me three years after the accident he stated that the pain was steadily increasing and had been much more severe during the last six months. A radiograph taken at this date (Plate, Fig. 1) showed an ununited fracture of the scaphoid, with some vacuoles in the bone. There was no arthritis.

I discussed the question of surgery with him as I thought that the damage was of such long standing as to make it unlikely that conservative measures would help. However, he was extremely keen to keep at his work, and agreed to give prolonged splinting a trial.

A leather-covered aluminium "cock-up" splint was therefore devised, of which the dorsiflexed portion fitted into the centre of his palm, and the arm portion was kept in position on the flexor surface of the forearm by a laced leather casing (Fig. 2). This allowed complete freedom of movement to all fingers and to the thumb. He wore this continuously for six months, being able to do all his work as a metal turner. The splint was removed only for the purpose of washing his hand, and during such times dorsiflexion was strictly maintained. There was some slight skin trouble from pressure and sweat, but with care and the use of methylated spirits and a dusting powder he was able to prevent the skin from breaking, and he strictly kept the correct position for six months. All pain disappeared within three weeks, and he felt but little inconvenience from the wearing of the apparatus.

A radiograph taken at the end of that time (Fig. 3) showed apparent union, and, no clinical sign of tenderness being elicited, the splint was discarded.

On reading Mr. Woods's case I re-examined the patient in February, 1938. He stated that he had had no further pain and that functionally his wrist was normal. Clinical examination confirmed this, and a further radiograph showed "bony union of the scaphoid with complete continuity of the internal border of the bone. There was considerable irregularity of the external surface representing the vacuolated areas noted at the first examination."

COMMENTARY

The surgical procedures suggested for the treatment of delayed union of these cases are by no means simple or

devoid of risk, and the results obtained are not universally satisfactory. So long as the diagnosis of "sprained wrist" is made without the exclusion of a fractured scaphoid by x-ray films, so long will these cases of delayed union occur. It would therefore appear that surgery in these cases should not be advised until a reasonably prolonged trial of conservative measures has been made. A man's ability to carry on at his work during such treatment is of great importance.

The Diagnosis of Large Ovarian Cysts

(WITH SPECIAL PLATE)

The differential diagnosis of an ovarian cyst is usually perfectly simple, but there are a few cases in which laparotomy must be undertaken to confirm it.

For purposes of description it is customary to divide ovarian cysts into three groups according to their size: (1) the small ovarian cyst, capable of lodging in the pelvis; (2) the medium-size cyst floating free in the abdominal cavity; (3) the enormous cyst filling the abdominal cavity, displacing the intestines. It is with the third group, or largest tumour, that this note deals.

The differential diagnosis between ascites and an enormous cyst which completely fills the abdomen, flattening the gut against the posterior abdominal wall and having a single large loculus in front, may be impossible by ordinary clinical examination. Such a cyst will not show the abdominal wall lifting off its capsule in respiration; it will give rise to dullness all over the abdomen, and often it is possible to elicit a fluid thrill through it. Ascites may cause dullness which is absolute and complete over the whole abdomen owing to the gut being "drowned" in the excess of fluid; as a result the sign of shifting dullness cannot be elicited. Paracentesis of the abdomen is of no help, for cells may be present in both ascitic and ovarian fluid, and pseudomucin does not always appear in the latter.

It may be impossible clinically to distinguish between marked obesity and neoplasm, for the former gives rise to abdominal protrusion, a feel of resistance on palpation, and, occasionally, complete dullness on percussion. The diagnosis is readily made, however, by injecting iodatol (B.D.H.) through a Keyes-Ultzmann cannula into the uterine cavity. An anaesthetic is rarely necessary, but the patient must be transferred to a radiographic department and placed on a table fitted with a Potter-Bucky diaphragm. After the insertion of the cannula into the uterus, preparation to take the radiograph should be made before injecting the iodatol. Two or three films should be taken, without moving the patient, after the injection of varying amounts of iodatol—namely, 4 to 5 c.cm., 10 c.cm., and 15 c.cm. It is essential that enough oil be injected to ensure the filling of the uterine cavity and the tubal lumina.

In the case of ascites or simple adiposity the lengths and outlines of the Fallopian tubes would be approximately equal (Plate, Fig. 1), but in the case of a large ovarian cyst one tubal lumen would be seen to be greatly elongated and to extend above the brim of the pelvis in the direction of the upper abdominal cavity (Plate, Fig. 2).

Surgeon, Liverpool Royal Infirmary.

An Unusual Case of Bilateral Digital Epiphyseal Deformity

(WITH SPECIAL PLATE)

The rarity of this condition seems to me to warrant its publication. I personally have not encountered another example.

The case is that of a healthy girl aged 12. At the age of 3 she fell downstairs, but sustained no injury to her hands. For the past two years deformity of the index fingers has been noticed at the proximal interphalangeal joints, with medial deviation of the fingers. The joints have become thickened, and she was brought to see me at the Orthopaedic Institute, Oldham, on account of pain and deformity.

X-ray examination (see Plate) revealed a medial subluxation of the middle phalanx and a peculiar angulation of the epiphysis of the middle phalanx. There is, so far as one can see, no fragmentation of the epiphysis. The base of the shaft of the middle phalanx is markedly indented by the angular epiphysis. The distal articular extremity of the proximal phalanx is a little "pointed" on its medial side, and this "point" corresponds with the apex of the epiphyseal angulation.

The aetiology is obviously a matter for speculation. One may exclude trauma, as the condition is bilateral and symmetrical, and no other finger or epiphyseal plate is involved. Although the deformity has only been noticed for the past two years it is quite possible that the condition may be due to an abnormal intra-uterine position of the proximal interphalangeal joints of the index fingers, producing a mild subluxation. The position could be maintained *in utero* by the terminal phalanx of the index finger being tucked under and grasped by the flexed middle finger.

Manchester.

HENRY POSTON, M.Ch.

Congenital Deformities of Hands and Feet

(WITH SPECIAL PLATE)

The following case, radiographs of which are reproduced in the Special Plate, may be considered of sufficient interest to be placed on record.

The case is that of an Egyptian boy, aged 11, of the fellahin class, who came to this hospital for treatment for ankylomiasis. It is curious that both feet and both hands should all have such similar congenital deformities.

He can grip quite strongly with his hands and perform all necessary actions. As he is illiterate he cannot write, anyway. He stands and walks well, and does not get unduly tired, though he has no arches to his feet. He does not go about barefoot like most of his fellows, but wears a pair of large old shoes to hide his feet, which rather resemble those of an ostrich or emu. The outlines of the soft parts and the bony defects can be seen quite clearly in the radiographs, for which I am indebted to the radiologist of this hospital.

C.M.S. Hospital,
Old Cairo.

Full-time Extra-uterine Pregnancy

(WITH SPECIAL PLATE)

Cases in which extra-uterine pregnancy reaches full time without tubal rupture are seldom met with. The case here recorded was of this variety, but our main object in making this brief communication is to exhibit an x-ray photograph which is probably unique.

CASE RECORD

The patient was admitted to hospital with a history that she was beyond full time and labour had not come on. Throughout the course of pregnancy there had been no symptoms to suggest that pregnancy was other than normal. As a result of abdominal examination it was thought that the patient was about seven and a half months pregnant and that she had probably erred as to the date of confinement. As time went on it was found that the child was not increasing in size, and as the foetal heart could not be heard it was decided that an examination should be made when the patient was under the influence of a general anaesthetic. It was then discovered that the case was one of extra-uterine pregnancy which had gone beyond full time without tubal rupture. We thought that, if this were so, an interesting x-ray photograph might be obtained, and consequently the uterus was filled with lipiodol so that that organ and the abdominal contents might be photographed by Dr John Reid. It will be seen from the illustration on the Plate that some of the lipiodol not only filled the enlarged uterus but passed along the left Fallopian tube. As the lipiodol had failed to enter the right tube it was concluded that this structure contained the foetus. In the radiograph the child can be seen lying transversely. At operation it was found that loops of ileum and omentum were adherent to the unruptured right Fallopian tube. The vessels in the omentum had undergone considerable enlargement. When these attachments had been liberated the tube with its contents were removed *en masse*. On opening the tube it was found that the liquor amnii had been absorbed. The patient made an uneventful recovery.

Accidental Vaccination of the Nose

(WITH SPECIAL PLATE)

Accidental vaccination is a well-known occurrence. We are recording this case, however, because it presented such a dramatic picture that it might have given rise to considerable difficulty in diagnosis.

CASE HISTORY

When seen in consultation on March 8 last the patient, a married woman aged 31, gave the following history. For about six weeks she had had a small fissure at the corner of her left nostril. On February 28 she began to notice enlarged and painful glands in her neck, especially on the left side. Two days later her nose became swollen and rapidly got worse, with vesiculation on the lower end and such oedema that her eyes were almost closed. She felt ill, and had a temperature of 101° with throbbing pain in her nose. Further inquiry into the history revealed that she had had a baby vaccinated on February 12, and the dressing had first been removed on the 23rd—that is, five days before the mother's first symptoms. The mother had never been vaccinated.

On examination she presented an acute inflammatory lesion of the nose, with such a degree of oedema of the face that one's first thought was of anthrax. The nose itself was bulbous at the tip and crusted, the margin of the ulcerated area showing pustules resembling those of variola. On the left cheek was a small group of vesicles (see the photograph, which unfortunately was taken after the most severe oedema had disappeared).

The patient was confined to bed after receiving a small dose of x rays (150 r). She was treated with perchloride of mercury fomentations and given 7½ grains of prontosil thrice daily. A week later, on March 14, the swelling and inflammation had subsided and she merely had a little crusting. When seen again two months later the lesions had completely healed, but she was left with a group of small round superficial scars on the tip of her nose.

An attempt was made during her illness to detect the virus by inoculating a rabbit, without definite result; but as the lesion was secondarily infected and had previously been treated with antiseptics a positive finding was unlikely.

COMMENTARY

This case when first seen was so fierce in appearance that it might easily have been mistaken for a more serious condition. The intense surrounding oedema suggested a malignant pustule, but there was no central black slough. Another possibility was a primary chancre, but the rapidity of onset, the history of vesiculation, and other points made this unlikely. Finally one considered the diagnosis of a carbuncle, but here again the vesicular onset and the pustular margin of the lesion did not quite meet the case. On the other hand, the history of a child's recent vaccination and the resemblance to an ordinary vaccination lesion made the diagnosis fairly probable, and this was confirmed by the course of the illness and the final scar that resulted.

Spasm of the Central Retinal Artery

The following case notes may be considered of sufficient interest to merit publication.

CASE RECORD

On August 31, 1938, at 6 p.m., a man aged 57 consulted me about sudden blindness in his right eye. He said that two hours previously, while motoring, he discovered he could not see with his right eye, and that closure of the left eye almost led to an accident.

On examination I found that his left eye had 6/9 vision and in all respects was quite normal, except for a low degree of retinal arteriosclerosis. The right eye showed a semi-dilated pupil which did not react directly to light. Vision in this eye was reduced to bare "perception of light." Ophthalmoscopic examination revealed that the retinal arteries were markedly contracted, that the calibre of the veins was about normal, and that there was generalized oedema of the retina, especially around the posterior pole. I made a diagnosis of embolism and advised immediate operation. To this he agreed. He was a healthy man with no history of illnesses.

The patient was admitted to hospital and I performed the following operation at 6.20 p.m. I first gave him a retrobulbar injection of acetylcholine. Ten minutes more were taken up in preparing the eye and washing it. Five per cent. cocaine was instilled into the eye. A keratome was pushed into the anterior chamber and the aqueous rapidly evacuated. He was then given an ampoule of amyl nitrite to breathe, and massage of the globe was carried out. I had hoped to watch events in the fundus on the table, but the cocaine produced some exfoliation of the corneal epithelium and so prevented a clear view. The eye was bandaged and the patient put to bed. Next day with the affected eye he could see the stripes on my tie and see "hand movements." On the following day—that is, two days after the operation—he could count fingers at three feet. His visual field was full.

The patient was sent home on September 5, and on the 6th his doctor informed me that his blood pressure was 220 systolic. On September 7 vision in his right eye was 1/60, and his visual field was normal. The screen test showed a small central relative scotoma extending to 5 degrees around the fixation point. The patient was put to bed and received treatment for his raised blood pressure.

I last saw him on September 30. His right vision was then 3/60, but only by holding his eye in extreme abduction. I expected to find a sector defect in the field corresponding with the branch blocked by the embolus. Absence of such defect has made me alter my diagnosis to one of spasm.

Reviews

MANUAL FOR BOARDING-SCHOOL DOCTORS

Medical Practice in Residential Schools. A Manual for Medical Officers and Others. By F. G. Hobson, D.S.O., D.M., F.R.C.P. (Pp. 284; 8 figures; 3 plates. 10s. 6d. net.) London: Humphrey Milford, Oxford University Press. 1938.

Medical men attached to boarding-schools have long felt the want of a textbook devoted to their special needs, both in dealing with the particular diseases which are common to such institutions and with the administrative problems they present. In *Medical Practice in Residential Schools* Dr. Hobson has produced such a work, which will assuredly find its place on the shelf of every school doctor for handy reference. The chapters dealing with the disorders and diseases of school age are concisely written and in a manner the school doctor will find most helpful. The particular methods of organization in times of epidemic infection which are needed for efficient control and management are fully dealt with and cover very thoroughly this responsible side of a doctor's duties. And no one who has not had the experience of dealing with an epidemic in a boarding-school can appreciate how grave those responsibilities are and how much they tax the resources of those in charge. The chapters on measles, diphtheria, and the streptococcal infections are of particular interest and value, if one may select from so many excellent examples.

The book will certainly become a standard work of reference, and in future editions we shall hope to see a wider field covered. In the first place there is a sense of disappointment that from the preventive aspect alone more emphasis is not directed to the need for physical education as a necessary part of school life. The duty of training and developing the adolescent body to its best capacity is now a recognized part of education—as should be the teaching of biology. If we are to teach a boy or girl to cultivate health in a positive sense the foundation of such knowledge must be instruction in the functions of the body and mind. The chapter on nutrition, excellent as it is, seems not sufficiently directed to school problems. The school doctor is often not consulted at all in such matters. Economy at the expense of food, extras (especially fresh fruit as an extra), cooking and serving meals, the relation of meals to games and work, are all special problems bearing on school work. On many of these points the school medical officer's hands would be strengthened if he could quote an accepted authority.

A chapter could well be written on the basic handicap under which the school doctor labours by virtue of his position. He holds his post at the will and pleasure of the headmaster. He has as much voice in deciding questions of diet, bed spacing, and the like as he can persuade his headmaster to allow him, which is sometimes none at all. Heads of schools who have their own ideas on health questions are not unknown. The headmaster who "believes in" this or does not "hold with" that has no one to say him nay. Again, what applies to headmasters is even more true of parents. The unfortunate doctor has to pay lip service to every kind of crank and fetish in the field of treatment of disease. One small point we would plead for. The decision as to paracentesis of the drum in cases of otitis media should be based on evidence of rising pressure shown by bulging of the drum.

Why may we not have this point in our textbooks and impressed on the student?

We commend Dr. Hobson's book whole-heartedly to all who are interested in this branch of medicine.

CURTIS' "GYNECOLOGY"

A Textbook of Gynecology. By Arthur Hale Curtis, M.D., Professor and Chairman of the Department of Obstetrics and Gynecology, Northwestern University Medical School. Third edition, reset. (Pp. 603, 318 figures 30s. net.) London: W. B. Saunders Company 1938

All who are already familiar with this textbook will be warm in their welcome of the latest and best edition. New readers, be they students or graduates, will find it most complete and satisfying. The previous work has been entirely rewritten, with eight new chapters added. These include an excellent introductory section dealing with the female pelvic anatomy, followed by a brief survey of the embryology of the generative organs. Probably the most valuable addition is the section dealing with gynaecological endocrinology, in which the present conception of hormonal activity and interrelationship is lucidly summarized and well illustrated. The chapter entitled "The Gynecological Patient Presents Himself" remains a feature of the book. Students and practitioners alike will find these pages filled with invaluable counsel, dealing as they do with those fundamental, but often overlooked, principles upon which both sound training and sound practice must be based.

Reference to sulphanilamide therapy, with due emphasis on the dangers of indiscriminate and uncontrolled administration of the drug, brings the chapter on "Infectious Processes" up to date. In dealing with the relation of cervical infection to sterility the author advocates amputation of the cervix in those cases of cervicitis in which no other cause for the sterility can be discovered, but makes no mention of the dangers of subsequent abortion should a high amputation be performed. The section dealing with puerperal sepsis gives emphasis to autogenous infection from vaginal organisms at the expense of the "droplet infection" theory. Reference to the valuable bacteriological and clinical work on puerperal sepsis performed in recent years at the Queen Charlotte's Isolation Hospital would improve this section of the book.

Tumours of the uterus and adnexa are admirably dealt with from every aspect, including a valuable and concise section dealing with the place of radiation therapy in the treatment of fibromyomata. The position of radical surgery and radiation in the treatment of carcinoma of the cervix is impartially discussed. Due and timely emphasis on the danger of radium in unskilled hands precedes a summarized account of the various techniques in common usage. Injuries to the pelvic floor and vaginal plastic surgery are splendidly described and illustrated. Sterility is fully discussed, and the arresting, though debatable, claim made that the best time to diagnose the condition is before marriage. Rubin's test is given preference to radiological investigation of the tubes, but the danger of wrongly interpreting the results of the former test is not mentioned, although in the past many patients have been agreeably surprised and many surgeons embarrassed by Nature's reply to the verdict of "blocked tubes."

From beginning to end this is an excellent work, and must be regarded as one of the finest textbooks of gynaecology.

CHEVALIER JACKSON

The Life of Chevalier Jackson An Autobiography. (Pp. 230, illustrated 15s. net.) New York and London: The Macmillan Company. 1938.

The childhood and youth of Dr. Chevalier Jackson were passed in circumstances so straitened as to amount at times to actual want. His father had become saddled with a heavy load of debt, due to embezzlement by one in whom confidence proved to be misplaced, and the early years were overshadowed by this family misfortune. It has been said that a wealthy parent can give his son everything except the stimulus of poverty, but the reverse is not true because, in spite of *res angusta domus*, the parents of Dr. Jackson provided him with a very happy life at home. The tale of his sufferings at school and of the barbarous conduct of the older boys, as related in his autobiography, makes painful though fascinating reading, and the wonder is that the frail youth survived such treatment. The means by which the poor young man maintained himself as a student of medicine command admiration, and his adventures as a vendor of medical books, as a cod-fisher, and as a sea-cook prove his capacity both for endurance and for spinning a good yarn. There is not much told about the very early years of practice, but the determination to become a specialist was soon reached, and Dr. Jackson made a voyage to Europe in a Dutch ship in order to visit Morell Mackenzie in London. The horrors of that voyage are vividly described, but there is scarcely anything related about the sojourn in London, of which English readers would have been interested to know more. From this point onwards the career of Dr. Jackson is better known. The development of bronchoscopy at Pittsburgh, the translation to Philadelphia, and the creation of the professorial chairs are familiar to the medical world; but the financial difficulties and the recurring threats of pulmonary breakdown which had to be overcome are less well known.

Dr. Jackson has become a man with a mission, the mission being the spread of safe bronchoscopy, but he has had other missions as well. One of these was the struggle to get household lye, the cause of innumerable oesophageal strictures in American children, labelled as a poison. The ultimate achievement of this was attained in the face of a dead weight of passive obstruction rather than active opposition, and required an almost incredible amount of work, time, and money. Another interesting chapter of this autobiography tells the views of the author upon how assistants should be treated. These views have brought abuse and ridicule upon him, and while sympathizing with the liberality and generous spirit upon which these views are based and were put into practice, it must be admitted that they appear somewhat exaggerated. The assistant who could stand for long such treatment in full measure as here described without being spoiled would surely be something of a superman. There is a curious paradox in this book that while holding such views Dr. Jackson says scarcely anything about his assistants personally. For the reason given he must have the gift of choosing for assistants those with a touch of the saint in their composition, and the reader would have liked to know more of his personal association with them. Perhaps the reason for this omission is that it is only one of many, for the book might easily be double its length without tiring the reader. Dr. Jackson has been cunning enough to leave him wishing for more—more delightful tales and more brilliant illustrations—but he gets a sufficient picture of the man. The simplicity of his life, the beneficence of his work, and the greatness of

BRITISH MEDICAL JOURNAL

SATURDAY - NOVEMBER 12 1938

HEPARIN AND THROMBOSIS

The recent studies of blood coagulation are of immediate practical importance to the physician and the surgeon, especially the latter, and we welcome, therefore, the opportunity of printing in this issue the lecture on heparin and thrombosis delivered by Professor Charles Best of Toronto on his visit to England earlier in the year. We surveyed in these columns a few months ago¹ the work of Dam and others which indicates that the haemorrhagic tendency in jaundice and disease of the liver is due to prothrombin deficiency and can be repaired by the administration of the fat-soluble vitamin K. Prothrombin may be regarded as a ferment-precursor which, under the influence of calcium and tissue extract, is converted into the ferment thrombin; thrombin then acts on fibrinogen to produce the clot or fibrin. The conversion of prothrombin into thrombin and the action of thrombin on fibrinogen can be inhibited by heparin. It is a moot point whether heparin is a normal constituent of the blood and the natural anticoagulant, but there seems little doubt that it is the factor responsible for the incoagulable state of the blood in anaphylaxis and peptone shock. Heparin was discovered in Howell's laboratory in 1916, but its anticoagulant properties could not be utilized outside the laboratory until the last five years, when non-toxic preparations became available as the result of the work of Professor Best and co-workers in Toronto and Jorpes and his school in Stockholm. Jorpes² describes heparin as a polysaccharide of high molecular weight which also contains nitrogen and sulphur. It appears to act by influencing the physical condition of the prothrombin, and it can easily be precipitated out with agents such as protamine or toluidin-blue, when the blood at once coagulates. The purest preparations of heparin contain up to 40 per cent. of sulphuric acid. The metachromatic violet staining of mucus and cartilage by toluidin-blue depends on the presence of mucicetin—or chondroitin—sulphuric acid, and the reaction is characteristic of high molecular esters of sulphuric acid. Heparin gives this reaction in extreme dilution, and an identical reaction is given by the metachromatic granules of the Ehrlich mast cells of the tissues. There is a parallelism between

the content of the viscera in mast cells and the amount of sulphate split off by acid hydrolysis, and there is reason to believe that the mast cells are the site either of formation or of storage of heparin.

The pure heparin now available is eight to ten times as strong as previous preparations and yet is only the same price. It is non-toxic by injection, and 500 mg. can be injected intravenously into a rabbit without ill effect. It is stable, and with care solutions can be safely autoclaved, though it is easier to sterilize by filtration. Dosage at present is confused by differences in measurements of activity. One manufacturer defines the unit of heparin as "the activity of that quantity of material which will prevent the clotting of 1 c.cm. of cat's blood for twenty-four hours when kept in the cold." Another firm's unit "corresponds to that quantity of heparin which is necessary to maintain unclotted 1 c.cm. of recalcified citrated ox plasma, of a pre-determined clotting power, for four hours at 37° C." Now Best has arbitrarily assumed that 1 mg. of his pure substance is equivalent to 100 units, though it is not yet certain that preparations are always of exactly the same purity or that we can dispense with biological assay. These different units apparently differ by about 500 per cent., and until international standards have been agreed upon users of heparin will be best advised to think in terms of milligrammes of pure preparations. Heparinized blood appears to be suitable for the majority of laboratory tests, with the exception of the Wassermann reaction, and, as Wilander points out,³ the same blood specimen thus suffices for examinations for which otherwise separate samples of whole blood, serum, and oxalated plasma would have been needed. There is no risk of haemolysis and no change in the size or fragility of the red cells. The heparin is non-reducing and will not interfere with any chemical analysis commonly performed on blood. There is nevertheless evidence that the leucocytes and thrombocytes soon cohere and form floccules in heparinized blood, and white cell counts should therefore be made at once. With pure samples of heparin haematocrit values appear to be reliable, but more work must be done on the sedimentation test with heparinized blood, as some authors, including Ström,⁴ have found the results capricious.

Heparin can be used in blood transfusion either by adding it to the blood as it is collected or by injecting it into the donor. In the latter method the donor receives an injection of 1 mg. of heparin per kilo of body weight, and the blood is withdrawn five to ten minutes later. At the end of one and a half to two hours the coagulation time of the donor returns to normal. Widström and Wilander⁵

¹ *British Medical Journal*, 1938, 1, 1050.² *Acta med. scand., Supplement.*, 1938, 89, 139.³ *Acta med. scand.*, 1938, 94, 258.⁴ *Ibid.*, 96, 365.⁵ *Ibid.*, 1936, 88, 434.

report that heparin has been injected into the pleural space to promote the resolution of experimental pleurisy in rabbits. The efforts of the Toronto school have turned largely to the study of methods for protracting the action of heparin and maintaining the diminished coagulability of the blood for prolonged periods, so as to avoid the risk of pulmonary embolism after operations and to prevent clotting in vascular surgery. With intravenous injections little is gained by increasing the initial dose above certain limits, but Murray and Best¹ have shown that the time of action can be prolonged almost indefinitely—for thirty or forty days if necessary—by continuous intravenous drip. In man this is given through an ordinary steel needle, which stays in the same spot for three to eight days. "General heparinization" is the term employed to denote that the clotting time of the blood in all parts of the body has been increased, and this has been effected by a continuous intravenous injection. The term "regional heparinization" has been coined to describe the injection of sufficient heparin into an artery proximal to a suture line to affect the clotting time locally in that vessel and in the blood returning from that region, but not to change the clotting time of the whole blood stream. Subcutaneously large doses of heparin are effective, and it was therefore natural to apply the same methods² as have been successful in prolonging the action of insulin. A heparin-protamine complex proved unsuitable for injection, but benzidine-heparin shows a definite prolongation of action, and Jaques, Charles, and Best³ have demonstrated that with large doses subcutaneously coagulation is diminished for thirty to forty hours. Although protamine itself has an anticoagulant action it neutralizes heparin by combining with it to form an insoluble salt. This reaction cannot be used *in vivo* owing to the toxicity of protamine, but it provides a method for treating blood for the presence of heparin *in vitro*.

The introduction of heparin has enormously simplified certain important experimental techniques in animals, such as transplantation of organs and exchange transfusions. Its most obvious applications to the human "animal" appear to be in arterial and venous surgery and in the prevention of post-operative thrombosis and embolism. Murray and Best have shown that if regional heparinization is used arteries and veins which have been sectioned and then sutured remain patent in about 80 per cent. of cases. If the lumen can be kept patent for seventy-two hours the suture lines heal and there is no longer a tendency to thrombosis or clotting at the site. Embolectomy can now be carried out many hours after the lodgment of the clot, as hepariniza-

tion will prevent clotting while the damaged intima is recovering. The prevention of post-operative thrombosis is more difficult to assess, but heparin has been used with complete success in Toronto in the after-treatment of fractured neck of the femur, prostatectomy, splenectomy, and other major abdominal operations in which thrombosis and embolism are peculiarly common. It is of course necessary, before beginning general heparinization, to wait four to twenty-four hours to allow the operation of the normal processes which control bleeding. Heparin is given at the rate of approximately 10 mg. per hour for seventy-two to 120 hours, and as 10 mg. of heparin can be obtained for one shilling one obstacle we previously referred to,⁴ when we stated that "the only difficulty that will face would-be users is in obtaining good heparin at any but an almost prohibitive price," no longer exists. Professor Best declares his intention to push ahead with experimental studies in the hope that further clinical applications will manifest themselves, but in the field from which he has already gathered so rich a harvest a good deal remains to be gleaned, and clinical workers have much to occupy them in repeating in man the procedures Professor Best has carried out in animals, in discovering if heparin plays any part in morbid conditions of the blood, and in determining its sphere of usefulness in the clinical laboratory.

CODEINE AS A HABIT-FORMING DRUG

It is common knowledge that international control of the traffic in opium alkaloids has been greatly complicated by the enterprise and skill of organic chemists. The conversion of morphine into heroin was the first important step in the synthetic production of drugs of addiction, and more recently at least three habit-forming drugs (dicodide, eucodal, and acedicone) have been produced from codeine. This difficulty was dealt with by supervising the wholesale trade in codeine, but since the latter drug was believed not to be habit-forming its retail trade was not regulated. This step resulted in a great increase in the popularity of codeine for use in such medicaments as cough tablets, and it is now estimated that the therapeutic use of codeine is about three times as large as that of morphine. The quantities of codeine required are obtained by preparing it synthetically from morphine. In the last few years disturbing evidence has been accumulating from various sources, and in particular from Canada, which indicates that codeine itself can be used as a drug of addiction, and that the remarkable increase that has occurred in the world production of codeine

¹ *Ann. Surg.*, 1938, 108, 162.

² *Acta med. scand., Supplement.*, 1938, 80, 190.

⁴ *British Medical Journal*, 1936, 2, 547.

is partly due to this fact. A summary of the known facts about codeine addiction recently prepared by Dr. P. Wolff¹ is therefore of considerable interest.

At the Hague Conference in 1912 it was decided not to include codeine among the drugs of addiction. The experts (one of whom was Dr. Wolff) appointed by the League of Nations to prepare evidence for the Conference on the Limitation of the Manufacture of Narcotic Drugs in 1931 gave the opinion that codeine was practically harmless as regards the production of drug addiction. This opinion was supported by substantial evidence, for extensive investigations undertaken at various times in the United States had revealed few, if any, certain cases of codeine addiction. Thus Treadway in 1930 analysed carefully 1,660 cases of drug addiction and found only a single case of codeine addiction. The situation at that time was that although morphinists, when deprived of morphine, might use codeine as a substitute, yet primary addiction to codeine was extremely rare. Dr. Wolff indeed states in this present article that only seven cases are known of primary addiction to codeine taken by mouth. The situation has changed recently by the development of subcutaneous or intravenous administration of codeine. That something is wrong in regard to the consumption of codeine is indicated by the fact that the figure per million inhabitants is about ten times as great in Canada and in France as in Great Britain; moreover, the annual imports of codeine into Canada have increased about threefold in the last decade. Investigations in Canada have shown that morphinists use codeine injections as a substitute for morphine. Experiments on morphinists also showed that codeine injected parenterally alleviated the symptoms set up by withdrawal of morphine and that abstinence symptoms occurred as soon as the codeine was stopped. An even more serious fact is that primary addiction to codeine injections has been proved to occur. The Canadian Government is taking steps to control the retail sale of this drug, and the problem of the chances of the occurrence of codeine addiction is being investigated in several other countries.

Dr. Wolff concludes his article by pointing out that there is little likelihood of codeine, when taken by mouth in the usual therapeutic doses, leading to addiction. He suggests that codeine should be avoided as far as possible in the medical treatment of persons who have formerly been addicted to morphine or of persons who are constitutionally predisposed to drug addiction.

INDUSTRIAL HEALTH RESEARCH

The eighteenth annual report of the Industrial Health Research Board¹ differs from its predecessors in that it not only contains the usual report of work done during the current year, but has also a summary of the main results achieved during the twenty years for which the Board has been in existence. An introduction to this summary traces briefly the gradual changes of outlook through which the Board has passed during these years. When the Health of Munition Workers Committee was formed in 1915 very little was known of the physiological laws governing industrial efficiency, and work proceeded in many cases under conditions as to hours, methods of work, and environment which were definitely detrimental both to the health of the operatives and to production. The committee gained so much valuable knowledge that it was decided that similar investigations ought to be maintained in post-war years, and accordingly the Industrial Fatigue Board was set up under the auspices of the Medical Research Council. At first the Board was mainly concerned with problems of fatigue arising from long hours of work, but later on this subject assumed less importance, and the special interest of the Board in problems of health was emphasized by substituting the word "health" for "fatigue" in its title. Moreover, the character of industry in general had changed considerably owing to the rapid advances of mechanization and the growth of light repetition work at the expense of heavier manual work. This put a premium on manual dexterity, and the "speeding-up" sometimes introduced was apt to react on the health of the workers, and especially on their spirits. The second part of the report, dealing with current research, describes a number of interesting investigations, only a few of which can be referred to here. Observations on the vision of a group of industrial workers showed that well over half had errors of refraction, three-fourths of which were uncorrected. It is important to ascertain if such proportions are characteristic of industry in general, and the Board therefore decided to extend the investigation to other groups of workers. The investigations now being made on heating and ventilation are mostly concerned with work at high temperatures, such as are met with in coal mines. It is interesting to note that in deep mines the effects of radiation may be substantial, the rock surfaces being sometimes 20° F. warmer than the air. The work on accident-proneness continues, with special reference to motor transport drivers, and it is claimed that the tests now used are to some extent predictive and should be of use in selecting new drivers. Studies of vocational aptitudes are being made in respect of temperament, vocational wishes, intelligence, and mechanical ability, both in adults and in juveniles of both sexes. Finally, occupational sickness is the subject of several investigations, the most important of which relates to a comprehensive inquiry into pulmonary disease in South Wales coal miners. It involves the investigation of cases of silicosis, the air-borne dust in the mines, and their atmospheric conditions.

POST-MORTEM CHANGES IN BONE MARROW

The examination of the bone marrow by means of sternal aspiration has not only increased our knowledge of many haematological conditions but has also made apparent fallacies in our conceptions of normal marrow cytology. It has long been recognized that the study of human marrow obtained post mortem was unsatisfactory, as changes took place which rendered the staining of the cells difficult, and although fixed sections are excellent for giving an impression of the distribution and degree of cellularity, it was impossible by this method to study the cytology of the cells with that clarity which can be achieved in film preparations. It would appear, however, that after death changes take place not merely in staining properties but also in the apparent proportions of the various cells. In normal marrow obtained in life some 40 per cent. of the cells are neutrophil leucocytes, whereas in post-mortem material the majority of the cells are "round cells," commonly regarded as myeloblasts. This discrepancy has been recognized for some ten years, and was generally explained as representing an agonal outpouring of leucocytes from the marrow. Rohr and Hafter,¹ working in Naegeli's clinic at Zurich, offer a different explanation. They have performed sternal punctures at repeated intervals before and after death in a number of cases of non-haematological conditions and find no striking changes in the neutrophil content of the marrow in the ante-mortem state: but after death changes take place very rapidly. In all cases examined the neutrophil percentage dropped from the normal 40 to between 1 and 3.5 in less than twenty-four hours. In two hours the nucleus began to swell and at the end of four hours had become rounded, so that it was difficult to differentiate them from myelocytes, and shortly afterwards lysis began: further vacuoles formed in the cytoplasm, the cell outlines became obscured, and at the end of ten hours they merged into syncytial masses in which granules and nuclear debris lay. Similar changes were seen in the myelocytes, though to a lesser degree, whereas the myeloblasts remained unaltered for much longer; in fact this autolysis was proportional to the proteolytic activity of the cells and proceeded more rapidly in cases of chronic disease than those with acute conditions. In contrast to the neutrophils, the eosinophils showed practically no change in their form or number up to twenty-four hours, though in later stages autolytic changes also appeared. The investigators found no significant change in the number of erythroblasts, and they could be easily recognized many hours after death. But there were considerable alterations in the character of the cells; these were of two kinds. First, there was a great increase of cells whose nuclei showed karyorrhexis, and this break-up of the nuclear material began in the ante-mortem agonal state and reached a maximum within a few hours of death; it is interpreted as a degenerative toxic change possibly associated with a terminal acidosis. In addition to this there was evidence of post-mortem maturation of the cytoplasm, the proportion of acidophil (haemoglobinated) erythro-

blasts steadily rising during the first six hours. Rohr and Hafter observed little significant change in the megakaryocytes, and although there was an apparent increase in the number of reticulum cells their impression is that this is not an absolute increase but that the autolysis of the granulocytes makes the normally inconspicuous reticular syncytium more obvious. The importance of this carefully controlled work for morbid histology cannot be overestimated; if it is confirmed—and general observations make this more than probable—it must minimize the value of all detailed histological investigations on the bone marrow after death, and differential cell counts of post-mortem marrow may be regarded as almost valueless.

ANGIOID STREAKS—ELASTOSIS DYSTROPHICA

There has been considerable controversy as to the aetiology of the changes in the fundus which Knapp, in 1892, termed angioid streaks. The fact that different stages of the affection assume rather dissimilar appearances—haemorrhages, exudates, or pigment changes dominating the picture at different times—has not helped to clarify the issue, for on theoretical grounds different observers have implicated different processes, stressing one or other ophthalmoscopic feature. Histological studies have not been particularly helpful because of the difficulty in obtaining satisfactory material. This difficulty has been such that most of the older studies can be dismissed as not valid, for the diagnosis has not been beyond criticism in any of them. Interest in angioid streaks was revived on the description by Ester Grönblad¹ in 1929 of an associated skin lesion, the rare pseudoxanthoma elasticum. This observation has now been confirmed in practically all the cases of angioid streaks studied since then. It is of interest to note that in 1903 Hallapeau and Laffite,² in describing a case of pseudoxanthoma elasticum, reported the presence of what they called central retino-choroiditis. Apart from the inherent interest in this association, Grönblad's observation was of importance in implicating the membrane of Bruch as the primary seat of the affection, for in the skin condition the underlying lesion is extensive degeneration of the elastic tissue. In an excellent contribution by Böck³ histological confirmation of this supposition is advanced. Böck made a careful study of the eyes of a patient who showed the associated ocular and cutaneous conditions. Definite ruptures of the membrane of Bruch were clearly seen, and it is apparent that the appearance of angioid streaks must be due to these tears, while the various other phenomena seen in the fundus are secondary features. Further confirmation is found in the thesis by Prick⁴ published simultaneously and independently. Of even greater significance is the fact that both these authors report the clinical finding of vascular hypertension, and the finding at necropsy of extensive degeneration of the elastic

¹ *Acta Ophthalm.*, 1929, 7, 329; *ibid.*, Suppl., I, 1932.

¹ *Folia haemat.*, Lpz., 1937, 58, 38.

system in the larger systemic arteries, so that there is every justification for extending the eye and skin syndrome to include elastic tissue degeneration in the vascular system. The name elastosis dystrophica suggested by Böck seems warranted. These recent observations explain the haemorrhages so often seen in the fundus in cases of angioid streaks. They explain, too, the occurrence of haemorrhages in other organs, as noted by Prick and also by Law.³ Of particular interest is the presence in Prick's case of pseudo-bulbar palsy, the result of a cerebral arteriopathy—secondary to arterial elastic tissue degeneration. The possible relationship to diskiform degeneration of the macula is worthy of study, as Grönblad has pointed out, for the histological feature of this affection is a lesion of the elastic membrane of Bruch, and clinically appearances simulating those of diskiform degeneration are often seen in cases of angioid streaks. Interesting, too, is the fact that both angioid streaks and pseudoxanthoma elasticum have been known to be familial in character—a point particularly stressed since the association of the two conditions has been recognized.

MORTALITY IN BELGIUM

In these days no sensible person uses the word "race" if he can help it—unless he is interested in the turf. A statistician familiar with the great names in the history of statistical methods, recalling the fact that among the very greatest are de Moivre, Laplace, and Quetelet, two Frenchmen and a Belgian, and noting that French vital statistics are conspicuously inferior to those of England and Belgian to Dutch vital statistics, might be tempted to think that race, or culture, had something to do with the difference, as perhaps it has. But in Belgium the medical statistical organization has been recently improved, and the statistician of the Ministry of Public Health in his lucid account of mortality rates in Belgium⁴ is able to give much information. He follows the general lines of such reports as the text volume of our Registrar-General's annual review, but includes more detailed tables (such as appear in the tabular volume of our statistics). M. Selleslags has throughout made direct comparisons between Belgium and Holland, which are almost always favourable, and often very favourable, to Holland. Standardized to the age and sex distribution of Belgium the Netherlands rate of mortality in 1930 would have been 10.8 per 1,000; the Belgian rate was 13.3. As M. Selleslags puts it, Belgium pays an annual tribute of more than twenty thousand human lives. Here and elsewhere the implicit assumption is that the differences between the rates of mortality depend upon controllable factors, an assumption which is pragmatically valuable because improvement of public health and sanitary services must always do good. But we hope that this purely statistical study may be followed by an economic and sociological comparison of these neighbouring States, which can be made much more competently by a Dutch or Belgian man of science

than by a foreigner. We should suppose that the economic structures, principal industries, systems of education, etc., differ widely, and that these are very relevant factors. In an appendix the author gives a number of valuable tables. One of these would provide a good theme for a sermon on the vanity of human wishes. If one omits mortality caused by automobiles—that is, retains industrial accidents, accidental drownings, poisonings, etc.—the rates per 100,000 males in 1901–10 and 1933–6 were respectively 47.1 and 33.2, a great improvement. But in 1901–10 there was, statistically speaking, no mortality through motor-cars, and in 1933–6 the rate was 14.6. So the total mortality from accidents in 1933–6 was 47.8 per 100,000, a little greater than in 1901–10.

EXPERIMENTAL DROWNING

F. G. Banting and his associates at the Banting Institute have recently turned their attention to another method of saving the life of the drowned, as a result of their own observations¹ on the physiological factors involved. They describe two types of drowning: in one a period of apnoea and swallowing is followed by gasping and the entrance of water into the lungs, whereas in the other the gasping phase is never reached and death occurs with the entrance of very little if any water into the lungs, obstruction by spasm of the glottis being the predominant feature. Such spasm may be set up by the entrance of small amounts of water into the upper respiratory tract, and the asphyxia produced is severe and prolonged, associated with a gradual slowing in the pulse rate. Measures to overcome the laryngeal spasm—such as the introduction of amyl nitrite, the use of a tracheal catheter for insufflation with 20 per cent. CO₂ in oxygen, and atropine to neutralize the vagal effect on the pulse rate—all led to improved recovery rates in the experimentally drowned animals. Artificial respiration was maintained during these and other methods of resuscitation, and it is emphasized that in dealing with human cases it must be persisted in longer than may be usual and even "until rigor mortis sets in." The electrocardiograph shows that the cardiac complexes can be detected as long as twenty-five minutes after the heart sounds are inaudible through the stethoscope. A summary of the measures recommended runs as follows: "As soon as the patient is recovered from the water he should be held up so that water may drain from the stomach and lungs and then placed in the prone position. All foreign matter should be removed from the mouth and larynx, —false teeth, weeds, etc.—and the tongue pulled forward with a handkerchief or tongue forceps, and the Schafer method of artificial respiration immediately started. It is of vital importance that there should be a free passage of air in and out of the chest. Therefore, if this cannot be detected the larynx should be swabbed with 10 per cent. cocaine or a catheter passed into the trachea with the aid of a laryngoscope, if available, or even by the direct vision method. If artificial respiration is performed without an adequate air passage

¹ *Canad. med. Ass. J.*, 1938, 39, 226.

the pressure will cause rupture of alveoli, adding to the already heavy odds against the patient. If a tracheal catheter has been inserted initial suction of this tube will remove much of the foam filling the trachea and bronchi." Carbon dioxide (20 per cent.) in oxygen can be insufflated at the rate of 3 litres a minute, and in the type of drowning with little aspiration of fluid amyl nitrite blown down the tracheal catheter is regarded as "the most effective measure yet found." The injection of 40 minims of 1 in 1,000 adrenaline solution to assist the heart's action is also recommended, and atropine 1/30 to 1/25 grain should be given intravenously. These measures are applicable to all asphyxiated or electrically shocked patients with the additional modifications suggested for those who have been drowned. Once again it must be emphasized that, valuable as these additional methods may be, the most important in all three groups is "prompt, adequate, and prolonged artificial respiration."

THE SHWARTZMAN PHENOMENON

If a bacterial filtrate which on injection into the skin of a rabbit produces little reaction is also injected intravenously on the following day necrosis and haemorrhage occur at the site of the previous skin injection. This phenomenon was first observed by Dr. Gregory Schwartzman of New York in 1927, and since then has been exhaustively studied by himself and by many other investigators. In an important and useful work,¹ Schwartzman unifies much information hitherto only available in scattered form on a subject which has the merits of comparative novelty, undoubted mystery, and some promise of illuminating certain obscure problems of disease. The earlier chapters are a systematic exposition of the conditions under which the phenomenon is produced. The active principle concerned is of unknown nature, but its properties have been extensively studied; not all bacteria produce it, but, on the other hand, some substances other than bacteria will elicit the reaction in areas previously injected with bacterial filtrates. Perhaps the most striking difference between this phenomenon and others, such as that of anaphylaxis, connected with the effects of injecting foreign material parenterally is its utter lack of specificity in the sense that the two injections may consist of filtrates of quite unrelated bacteria. An extraordinary and quite distinct aspect of the subject is the occurrence of a similar reaction, sometimes leading to regression, in malignant tumours when a highly active bacterial filtrate is given intravenously; the possible bearing of this on treatment with Coley's fluid is obvious. The least convincing chapter is that in which the author strives to interpret some of the phenomena of naturally occurring disease in terms of this phenomenon. The suggestion that skin necroses in the sacral region in enteric fever, or certain haemorrhagic states, can be explained on these lines seems highly speculative. It has been shown

that an antibody which specifically neutralizes a corresponding bacterial filtrate is produced during recovery from certain infections in man, and titrations of therapeutic serum have been carried out on this basis with results differing from those obtained by estimating other kinds of antibody; there is some evidence that anti-meningococcal and anti-typhoid sera with a high capacity for inhibiting the phenomenon are correspondingly effective therapeutically. In spite of facts such as these, the bearing of which is after all only indirect, it does not appear that the Schwartzman phenomenon has yet been conclusively shown to have any exact counterpart in human pathology, and the fact that only the rabbit, of all animals so far tested, exhibits it typically and regularly seems an obstacle to drawing conclusions with a general application. In the bewilderment which the reader may pardonably feel over a subject so full of uncertainties he is unfortunately impeded further by the author's style, which is careless and obscure.

IN MEMORY OF OSLER

The fourth Osler Memorial Oration was delivered by Sir Humphry Rolleston at the sixty-ninth annual meeting of the Canadian Medical Association, held at Halifax on June 22, 1938. It was published in the *Journal of the Canadian Medical Association* (1938, 39, 313). The oration is of especial interest because it is written by one who knew William Osler well and deals with the latter portion of his life, which was spent as Regius Professor of Medicine at Oxford. Sir Humphry tells much about Osler, of his personality, of his charm of manner, of his humble-mindedness, of his desire to help, of his manifold interests, of his power of work, and of his resuscitation of a medical school which had almost become extinct. The oration is well worth the trouble it must have taken to produce, and recalls to many the traits of a great teacher of medicine.

Dr. H. Morley Fletcher left this country on October 28 for Australia, where he is going as representative of the Royal College of Physicians of London to the opening of the Royal Australasian College of Physicians in Sydney. The Royal College of Physicians has presented an illuminated address and a replica of the silver wand or caduceus which was presented to the College by John Caius in 1556.

The next session of the General Medical Council will open on Tuesday, November 22, at 2 o'clock, when the President, Sir Norman Walker, M.D., will take the chair and deliver an address. The Council will sit thereafter from day to day until its business is concluded.

Professor J. B. S. Haldane, F.R.S., will deliver the Lloyd Roberts Lecture on "Some Problems of Human Congenital Disease" at the Royal College of Physicians of London, Pall Mall East, S.W., on Thursday, November 17, at 5 p.m.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

CHRONIC MASTITIS

BY

CECIL ROWNTREE, F.R.C.S.

The condition generally known as mastitis, chronic interstitial mastitis, or cystic mastitis—to mention the most common names by which it is recognized—would be a relatively insignificant and unimportant disease were it not for the fact that in some of its manifestations it so closely mimics cancer of the breast, and that, furthermore, there is a widespread belief that it may be the forerunner of a malignant change in the affected organ.

Whatever its type and whatever its origin mastitis is almost invariably painful—not the severe throbbing pain associated with pyogenic infections of the breast, but a minor though none the less steady, nagging, neuralgic pain aggravated by movement or exercise, and influenced to some extent by the menstrual cycle. It is the pain that brings these patients to the doctor and not the accidental discovery of a painless lump, as is so often the case in cancer of the breast.

Mastitis is so varied in its manifestations, and the different types merge so gradually one into another, that it is very difficult to provide any satisfactory classification; but careful consideration of a large number of cases does permit some sort of selection of comprehensive clinical groups.

Subacute Mastitis

The best-defined group consists of cases of what should properly be described as subacute mastitis, characterized by painful swelling of a sector of the breast. The affected sector becomes tender, hard, and heavy, and acquires a cake-like rigidity, so that on manipulation it moves as one piece on the chest wall. A large part—as much as half—of the breast may be affected in these cases. This particular type of mastitis is generally unilateral; it is apparently more common on the right side than on the left, and is met with especially in women whose breasts are somewhat pendulous and who have recently engaged in some unaccustomed effort such as the first game of tennis of the season, spring-cleaning or similar strenuous exercise. In fact, it is pretty obvious that trauma is the determining cause in most of these cases; but trauma cannot be the whole story, for it is significant that the kind of mastitis met with in the tiny breasts of little girls just before puberty, and in boys too, closely resembles the type just described.

Pubescent Mastitis

These puberty cases provide an interesting and typical clinical picture, for here also the breast tissue becomes firm, tender, and rigid; but there is this difference—that the whole breast, such as it is, is involved, with the result that a little tumour is produced in the form of a flat disk with rounded edges and a thinner centre which closely resembles the shape of a nux vomica bean. It is characteristic of these cases that both sides tend to become affected, the second breast enlarging as the first gets better.

Mastitis in the Male

This bilateral involvement at puberty gives strong support to the suggestion of hormone imbalance as an aetiological factor in the disease, and stands in sharp contrast to the state of affairs in the adult male, where mastitis would appear to be almost invariably unilateral and almost invariably the result of trauma. Here also the clinical signs are striking and definite, for again the whole breast is involved, with the production of the bean-shaped mass already referred to. The shape of the swelling affords a useful diagnostic distinction from cancer of the male breast, which at any rate begins as an asymmetrical tumour of only a portion of the breast tissue.

Treatment of Subacute Mastitis

Subacute mastitis occurring in any of these forms tends to get well in a few weeks, but its progress may be aided by local applications of heat and belladonna and by firm support and pressure by brassière, bandage, or elastoplast. Protection from further direct trauma and limitation of use of the arm on the affected side are obvious adjuvants that should not be omitted. In cases where the breasts are large or pendulous it is important to insist upon a well-fitting brassière if recurrence of the trouble is to be avoided, and it is well to remember that these patients may be greatly helped by wearing a brassière in bed as well as on all occasions in the daytime.

These subacute cases are relatively uncommon types of mastitis that are comparatively easy to diagnose and to deal with, and they afford a striking contrast to the more common and the more difficult problems presented by the chronic cases:

Chronic Interstitial Mastitis

What are the predominating symptoms in this group? Unlike the adult subacute variety, chronic mastitis is often bilateral—a very important point when it is remembered that cancer is almost always unilateral; and more than one area of the breast may be affected—again a matter of importance when compared with cancer, which almost invariably starts as a single focus. The age distribution is fairly wide, for it is commonly met with from the early thirties until well after the menopause. It is not, however, seen in old age, and it is a fairly safe rule that after 65 or 70 most lesions of the breast are malignant.

Breasts which are the seat of chronic mastitis are in the main soft and pendulous, and it is the exception to find the disease in firm, well-preserved, and shapely organs. I have the impression that cancer shows no such discrimination. Enlargement of the axillary lymph glands is sometimes seen, but they are of the normal soft consistency, unlike the inelastic hardness resulting from cancerous infiltration.

Discharge from the nipple is not infrequent, and occasionally a small amount of yellow or greenish fluid may be expressed from both nipples although only one breast has given rise to discomfort.

Pathological Anatomy of Chronic Mastitis

For a clear comprehension of the problems occasioned by mastitis, a mental picture of what is going on or what may be going on in the affected breast is essential. This is, of course, not the place for a lengthy consideration of the pathological anatomy of chronic mastitis, but very broadly it may be stated that it is characterized by the formation of an excess of interstitial fibrous tissue and a tendency to cyst formation in the affected portions of the breast. At one end of the scale we see cases in which the development of fibrous tissue may entirely overshadow the cyst formation: the cysts are there but are few in number and microscopic in size, and the affected breast tissue is then a smooth homogeneous mass. At the other end of the scale are cases in which cyst formation predominates, and the clinical picture will merely present one or more simple cysts of any size between a pea and a golf ball.

Most common are cases in which fibrous tissue and cysts are more or less balanced, and the picture will be an irregular, shotty, and occasionally very hard mass which is made up of innumerable tiny cysts embedded in dense fibrous tissue. It is clear, too, that it is possible for this process of cyst-fibrous tissue formation to be present in more than one portion of the affected breast and to be at a different stage in each.

This thumbnail sketch of the pathological processes underlying chronic mastitis will serve to indicate how varied may be the clinical manifestations of the disease, and how difficult may be the task of the practitioner who is faced with the responsibility of deciding whether in fact it really is a case of chronic mastitis with which he has to deal, or whether it is something more serious. And a decision must be made at once, for it cannot or should not be deferred in order to await the effects of a period of tentative treatment.

Diagnosis of Chronic Mastitis

The finely nodular or shotty cases are generally easy of diagnosis: the patch tends to be sector-shaped, it is tender on manipulation, there may be more than one patch in the breast, and both breasts may be affected. The cystic cases, too, are often easily recognized; but there are wide variations, and whereas the true nature of a large, simple thin-walled cyst may be at once detected by its spherical shape, by its elasticity, and by the fact that the posterior hemisphere of the cyst may sometimes be felt bulging through the deep aspect of the breast, it is quite otherwise with solitary cysts firmly embedded in a thick mass of tissue in cases of fibrous mastitis. It may be impossible to distinguish these from carcinoma until after removal.

When fibrous tissue is predominant a hard mass develops which merges imperceptibly into the surrounding breast tissue, and gives, when grasped between the fingers and thumb, the impression of a definite tumour, but when palpated with the flat of the hand may not be apparent as a tumour at all. Great stress has been laid upon this last sign, but it is unsafe to attach too much weight to it, as certain cancers of the breast starting on the deep surface of the organ may present the same elusive characters.

It is when a nodule is of quite small size in cases of fibrous mastitis that the greatest difficulties in diagnosis are met with; indeed, there is no ordinary method of examination by which a very small cancer, a very small

cyst, and a very small mass of fibrous mastitis can be differentiated: and owing to the influence of widespread propaganda we are getting more and more of these early cases. Puncture with a fine hypodermic needle may demonstrate the fluid contents of a cyst: but the tiny ones are not easy to hit off in this way, and in doubtful cases our only resort is diagnostic removal of the suspicious mass followed if doubt still exists by histological examination.

Biopsy of Doubtful Breast Tumours

There are wide differences of opinion as to the wisdom of this procedure; indeed, many go so far as to lay down the rule that all suspicious breasts should forthwith be removed. This is surgery on totalitarian lines, and puts at a discount the long years of careful training with which most surgeons endeavour to prepare themselves. There is no convincing evidence which clearly indicates that there is danger in establishing the diagnosis by careful preliminary excision. It will be generally agreed that the patient should be spared if possible the ordeal of two visits to the operating table, and it is clear, therefore, that the diagnostic excision of breast tumours is best confined to those who have the knowledge necessary to enable them to recognize immediately the nature of the tissue removed, and the capacity to proceed with suitable operative treatment should the case prove to be malignant.

I recognize that this is a counsel of perfection and that those without much surgical experience must from time to time be faced with the necessity for removing one of these small masses for subsequent pathological examination. It is not always easy, particularly in large fat breasts; and a little practical point that I have found to be of great value is to fix the small tumour with a fine needle thrust into it through the skin before the incision is made. It is not easy then to lose one's way and to spend a long time searching for a little mass which can be strangely elusive in the surrounding fat.

In case the condition should prove to be malignant the gentlest possible handling is essential in order to avoid the possibility of squeezing cells into the neighbouring lymph or blood channels. Damage to the tissues also militates against that perfect healing of the wound which is so important if the preliminary excision is to be followed by a major operation at a later date. The most meticulous precautions should be taken to avoid infection of the wound, and it is well to adopt the additional safeguard of drainage in order to minimize the possibility of haematoma formation.

Treatment of Chronic Mastitis

To turn now to the treatment of chronic mastitis. It is obvious that in many cases it is necessarily surgical, because doubt as to the diagnosis imposes the necessity of removing the offending mass and thereby curing the disease or, at any rate, curing the symptoms and relieving the mind of both doctor and patient. While it is wise not to be niggardly in removing the portion that is under suspicion, there is no need at all in most cases for resection of wide areas of the breast.

Aspiration of Simple Cysts

In dealing with cases characterized by cyst formation it is always possible by aspiration through a stout hypodermic needle to empty individual cysts with a fair assurance that if the cyst be completely emptied it will not refill. Why, I do not know, but the fact is indis-

putable. But other cysts may develop, and although it may be possible to keep up with them by this procedure, the patient may become so distressed by the recurrent necessity for aspiration that it may be desirable to advise a limited amputation of the breast. If desired, this can be performed subcutaneously through a circumferential incision, leaving the nipple *in situ*; but I am bound to confess that the resulting area of depressed scar with the nipple perched somewhat precariously in the middle is to my mind more unsightly than the deformity left by a simple amputation with elliptical incisions which come neatly together in a linear scar. Complete symmetry is necessarily often obtained owing to the fact that multiple cystic disease of the breast tends to be bilateral and both sides may require amputation.

I am aware that I embark on somewhat controversial ground in advising the aspiration of simple cysts of the breast, but I have done it now so many times and for so many years with complete immunity from any kind of difficulty that I am convinced it affords a simple, safe, and effective method of dealing with them. There are two safeguards, however, that must be emphasized: first, the cyst must be completely emptied so that it collapses and entirely disappears, for if only half emptied it will return in a few weeks; moreover, if it is not possible to obtain complete collapse of a cyst by this means it indicates that there is something more than a simple cyst, and surgical exploration must be employed. The second safeguard is a most careful scrutiny of the fluid withdrawn. It may look like clear serum, it may be yellowish, or it may be green and turbid. None of these variations is of any significance, but if the fluid is blood-stained, then it means, or it may mean, an intracystic growth, and immediate surgical excision is indicated. In my experience this occurrence has been exceedingly rare.

One naturally asks oneself whether any treatment is possible that will stay the progress of multiple cyst formation, and I know of none when the cysts have achieved what one may term "clinical dimensions." But it is otherwise with cases of chronic mastitis where the cyst aspect is not clinically obvious; for there are two lines of attack which appear to hold out some hope of arresting what is, after all, a progressive disease. The first is the application of x-ray therapy, which does seem to be of value: it certainly diminishes pain, I think it softens the thickened tender masses, and I believe that it stays the progress of the disease. The second line of attack is based upon what would appear to be a well-founded view that all forms of chronic mastitis are to some extent dependent on hormone disturbance. The administration of hormone preparations such as theclol cannot at present be regarded as anything more than experimental, but it is obviously worthy of the detailed and extended trials that will be necessary before it is possible to come to any definite conclusion on the efficiency of the method in staying the progress of the disease.

Finally it should be emphasized that chronic mastitis is a relatively uncommon disease; or perhaps it would be more accurate to say that women present themselves for the treatment of chronic mastitis relatively seldom. It is less than half as common as cancer of the breast. Of any hundred women who come for treatment of chronic breast conditions sixty have cancer, ten such miscellaneous diseases as adenoma, lipoma, fat necrosis, and so on, and the remaining thirty have one or other of the manifestations of mastitis. It is a safe and wise rule, therefore, to regard any breast tumour as a carcinoma unless or until it has been proved by aspiration or biopsy to be innocent.

THE STATE OF THE PUBLIC HEALTH

CHIEF MEDICAL OFFICER'S REPORT*

[SECOND NOTICE]

A summary of the earlier chapters of Sir Arthur MacNalty's Annual Report for 1937 as Chief Medical Officer of the Ministry of Health appeared last week at page 957.

Medical Intelligence and Research

A list is given of over fifty committees on public health and medical questions on which members of the Ministry's staff have served. Fourteen reports and memoranda of special medical interest have been issued during the year. Attention is also drawn to certain expansions in the work of the Medical Intelligence Section. The chief of these relates to the recently established liaison between the Ministry and the Central Council for Health Education, a body which was founded in 1927 to co-ordinate the work of health publicity, etc.

Research in medical statistics has revealed, among other things, that simple violence killed more than half as many males as all the infectious diseases taken together, that a very large proportion of these violent deaths occurred on the roads, and that just as there are accident-prone persons so there are sickness-prone persons—that is, persons for whose abnormal sickness rate no merely physical grounds can be assigned and malingering can be excluded. Other matters dealt with in this chapter range from an account of rat destruction on ships, docks, quays, etc., and rat-flea surveys at ports to the problems dealt with by the International Sanitary Convention for Aerial Navigation. Full particulars are also given of port health administration during the year and of international health work.

Tuberculosis in 1937

Though there was a slight increase in the number of deaths from all forms of tuberculosis the standardized death rate for 1937 remains the same as for 1936, when the figure of 657 per million was the lowest ever recorded. It is the most striking example known of reduction of the mortality of a disease in our own time.

There were 28,529 deaths from tuberculosis certified in 1937—261 more than in 1936. The slight rise in mortality from pulmonary tuberculosis was directly associated with the epidemic of influenza at the beginning of the year. There was also some increase in the mortality from non-respiratory forms of tuberculosis. During the year 59,918 new cases of tuberculosis (all forms) came to light in England and Wales as compared with 59,269 in 1936. The number of new cases and contacts examined for the first time by tuberculosis officers in England and Wales was 161,382, an increase of 6,158 over 1936 and 12,444 over 1935. These figures probably indicate that greater use is being made of the service for suspected cases. It is hoped that the intensive educational campaign carried out under the auspices of the Ministry early in 1938 will result in patients seeking advice at an early stage of the disease when recovery is most probable. The chapter ends with a brief note on the surgical treatment of pulmonary tuberculosis and a discussion of bovine infection.

Venereal Diseases

There is evidence that measures taken under the Venereal Diseases Regulation are lowering the incidence of fresh infections with syphilis in this country. Cases of congenital syphilis among infants show a further reduction, and deaths from such late effects of syphilis as general paralysis of the insane and locomotor ataxia show,

FIG. 1.—Radiograph of both hands.

FIG. 2.—Radiograph of both feet taken from the dorsum.

S. J. CAMERON AND H. J. THOMSON: FULL-TIME EXTRA-UTERINE PREGNANCY

Radiograph showing lipiodol in the enlarged uterus and the left Fallopian tube, with the full-term foetus lying transversely in the unruptured right Fallopian tube

S. G. BEDFORD AND F. F. HELLIER: ACCIDENTAL VACCINATION OF NOSE

This patient had never previously been vaccinated. The photograph was taken after most of the oedema had disappeared.

in males, a further fall though there is not much change as regards females. The figures for gonorrhoea show a slight increase over those for 1936, but this may be due to a larger proportion of infected persons resorting to treatment centres. An account is given of the new and promising method of treating gonorrhoea by the sulphonamide group of compounds, and a necessary warning is given against their use except under medical advice.

The Cancer Problem

There is still no indication of any decline in cancer mortality, and the year 1937 once more shows increases over the preceding year, both for males and females, though those increases are less than those manifested last year. The total number of deaths was 66,991 for both sexes compared with 66,354 in 1936, an increase of 637; the previous year's increase on its predecessor was 1,847. These mounting figures do not necessarily mean that the causes of the disease are becoming more prevalent year by year. Account has to be taken of the increasing longevity of the population whereby more people survive into ages in which the liability to cancer is greater, and of the increasing accuracy of diagnosis. It is pointed out that, until the wide-flung researches into causation bear more abundant fruit, our chief methods of attack are by early and accurate diagnosis and efficient treatment. Here, partly owing to advances in diagnosis, but more especially owing to the newer and more effective means of treatment, the outlook is now brighter than ever before. Apart from the progress of surgery, an increasing knowledge of the technique of treatment by radium and x rays has contributed to this result. The section closes with a discussion of the most promising lines of advance, and suggestions are made whereby the modern methods of diagnosis and treatment might be brought within the reach of a larger section of the population. It is essential that the provision of additional facilities be made known to both medical practitioners and the public, and people should be encouraged to seek advice and treatment at an earlier stage than is now often the case. Fortunately, there are signs that the provision of treatment in the radium centres has led to a greater demand for it.

Relation of Food to Health and Disease

Much work was done during the year on the subject of nutrition. The work of the Advisory Committee on Nutrition has been mainly concerned with an inquiry into family budgets, which is being conducted by the Ministry of Labour, the relation between income distribution and family expenditure on food, and quantitative dietary surveys. The League of Nations has published its final report on "The Relation of Nutrition to Health, Agriculture, and Economic Policy." Reference is made to certain surveys and investigations—namely, the dietary survey of the West Riding of Yorkshire, the ante-natal investigations in Blackburn and elsewhere, the collection of data in respect of measurements and clinical assessments relating to physical efficiency, and the rate of growth of babies. The Milk Nutrition Committee, whose first report was published early in 1937, issued a second (interim) report on the research done in schools in England and Scotland. Among other points brought out in this report is the fact that no constant differences were observed between the rates of growth of children receiving raw milk and those receiving pasteurized milk.

Suspected food poisoning outbreaks which came to the notice of the Medical Department of the Ministry numbered ninety-four, as compared with eighty-two in 1936 and 137 in 1935. On the subject of Salmonella infections it is pointed out that in many of the outbreaks the source of infection was not discovered. Suggestions are made as to how the work of investigation can be materially helped by those concerned in dealing with suspected cases of food poisoning. In con-

nexion with the purity of food, reference is made to contamination of food by fluorine and other substances, and advice is given on the home canning of vegetables. A note on the use of refrigerators points out that while these have many advantages danger may result from ignorance of their limitations: "refrigerators are not sterilizers," and the food must in the first place be sound, whether intended to be stored in a refrigerator or elsewhere.

Conclusion

In his final chapter Sir Arthur MacNalty draws together the various threads, and reviewing the vital statistics for 1937 states: "The vital statistician must consider long-range periods, and it does not disturb him if one year's mortality figures show a slight rise over the previous year, provided that the figures over a decade show reduction." This year a new function has been added to the Department, in that to the Ministry of Health has been assigned the responsibility for dealing with matters relating to the provision of hospital accommodation in England and Wales for the treatment of air raid casualties in the event of hostilities. For Scotland the Department of Health has assumed corresponding functions.

Among the appendices of more general interest may be mentioned Appendix A (Fatalities in the United States of America from "Elixir Sulphanilamide"), illustrating the tragic possibilities which may accrue from placing untested drug preparations on the market; and Appendix B (Advances in Knowledge of the Streptococcal Infections), the streptococci being a group of organisms which probably do more damage to the public health than any other bacteria.

HOSPITAL ZONES IN WARTIME

Following upon the International Red Cross Conference held in London last June, a committee of military and legal experts met in Geneva on October 21 and 22 to draw up suggestions for a convention for the establishment of hospital or sanitary zones in time of war. Eighteen countries were represented by about forty experts, some appointed by their Governments, some by their National Red Cross Societies, and a certain number by both. The British representative was Lieutenant-General Sir Harold Fawcus, Director-General of the British Red Cross Society. Other Governments represented were those of Germany, Belgium, Denmark, Latvia, Poland, Sweden, Italy, Switzerland, Yugoslavia, Turkey, and Brazil. Insurgent, but not Republican, Spain was represented. After a long discussion, in which the main contest lay between the military and the legal points of view, a convention was drafted which will be submitted to the Swiss Government with a view to the assembly of a diplomatic conference for approval of the convention and its attachment to the Geneva Convention of 1929.

New Draft Convention

The articles of the new draft convention lay it down that hospital localities or sanitary zones intended to receive the sick and wounded shall be protected and respected by the belligerents. This benefit is to extend not only to the land but to the air. They will be reserved to the medical services of the armies, to the exclusion of all other military uses. It is provided that they must be situated and maintained outside the field of operations, including the sea front, and sufficiently far from military objectives not to be in peril of bombardment. They must not serve as a refuge for persons who were not residing there before hostilities. The localities must be indicated visibly at their borders by the emblem of the Geneva Convention. In time of peace each of the parties to the new convention will communicate to the International Committee of the Red Cross a list of localities which it is proposed in time of war to assign for this purpose. At the

beginning or in the course of hostilities each contracting party must notify, again through the International Committee, the localities which it may be proposed to institute, specifying in an exact manner their position and boundaries. If the localities so designated are on a list which has been communicated to the International Committee at least three months before the beginning of hostilities any objections must be notified within three days from the receipt of such information, but if the localities did not appear in the pre-war list an interval of twenty days between notification and objection may be permitted. Other articles provide for the cancellation of the agreement with regard to a particular locality and the period which must ensue before such cancellation can become operative; also for a procedure of inquiry according to the articles of the Geneva Convention, in the event of dispute. In the case of the invasion of the country by an enemy the protected locality is to continue to be utilized as such, subject to the notification of opposition by the dispossessed belligerent.

The zones are to be subject to the control of a supervisory commission with at least three neutral nationals nominated by the International Committee and agreed by the State on whose territory the localities are situated. Each member of such commission may, at the discretion of its president, be given a specified area to supervise. It will be the business of the commission to see that the rules of the convention are observed, to draw the attention of the belligerents to any infraction, and if no notice is taken of such warning, the supervisory function may be withdrawn and the belligerent States be so informed through the International Committee. A further requirement is that the belligerents shall facilitate to the fullest extent possible the task of the commission, in particular by affording its members the necessary privileges and immunities in the exercise of their functions. On a complaint that the conviction has been violated by an enemy a contracting party may demand an inquiry under Article 30 of the Geneva Convention.

The history of this subject goes back to 1933, when the seventh Congress of Military Medicine and Pharmacy, held at Madrid, made a recommendation for the establishment of hospital towns and areas to give shelter to sick and wounded members of the forces in time of war. A commission of medical and legal experts met at Monaco in 1934 to formulate a draft, and the fifteenth International Red Cross Conference, held at Tokyo later in the same year, asked the International Committee and the National Red Cross Societies to consult their Governments with a view to stimulating action along these lines. A meeting of experts was held in 1936, at which further discussion of the problem raised a large number of essentially military questions, and a year later, at another meeting of experts, called with a view to the revision of the Geneva Convention, this question was again approached, and it was recommended that all national societies which had not yet communicated the opinion of their Governments should be once more consulted. This was done, and a report was made to the International Red Cross Conference in London last June (*British Medical Journal*, June 25, p. 1381, and July 2, p. 32), of which the recent meeting at Geneva is a consequence.

G. Barbagallo (*Policlinico*, 1938, 45, 230, Sez. Med.), who reviews the literature and records his personal observations on twenty-one cases, consisting of one of subacute endocarditis, six of undulant fever, and fourteen of typhoid fever, states that in some infectious diseases it is possible not only to isolate the pathogenic organism from the sternal bone marrow, but also to obtain it from the bone marrow when it cannot be found in the peripheral blood. Moreover, it is possible to cultivate it from the sternum at times when blood culture is not possible, as in advanced stages of the disease or when the fever is not very high. The technique of puncture of the manubrium sterni according to Arinkin's method and with Baserga's needle appears to be simple and harmless.

LUNACY AND MENTAL DEFICIENCY

BOARD OF CONTROL ANNUAL REPORT¹

Statistics of mental disorder and deficiency vary little from year to year. The curves for admissions and ascertainment tend to rise slightly, but not enough to cause misgiving. Far more mental defectives have to be dealt with than in years gone by, but that is because of the greater thoroughness with which such cases are reported to the local authorities. The population of mental hospitals rose during 1937 by about 2,000, but it is emphasized that this has no necessary connexion with the incidence of mental disorders in the general population, being merely the increase shown by the excess of admissions over the combined deaths and discharges.

One unexplained feature this year is that the reduction in the number of certified admissions to the mental hospitals, which was so marked in 1934 and 1935, has been checked, although at the same time there has been a rise in the number of voluntary admissions. The latter increased by just over 1,500, but admissions under certificate fell only by some 300. The total admissions to public mental hospitals were 26,892, the voluntary ones accounting for 8,414. At the end of 1937 the number of persons suffering from mental disorder—voluntary, temporary, and certified patients—notified as under care in England and Wales was 157,353, an increase of 1,831 on the figure for the previous year.

The death rate in the hospitals rose slightly to 7 per cent., an increase of no statistical significance, and the rate remains remarkably low when the high proportion of senile patients and patients in a physically enfeebled state is remembered. Diseases of the myocardium remain the largest single cause of death. There were only fifty-nine cases of enteric fever during the year, with twenty-five deaths. Tuberculosis of the respiratory system accounted for 539 deaths, a ratio of just over 4 per 1,000 resident patients. Out of a resident population of 136,721 patients in mental hospitals at the beginning of 1937, 9,544 were discharged during the year as recovered and 6,997 as relieved. The recovery rate per cent. calculated on the direct admissions was 31.2 (29.1 for males, 32.8 for females).

Out-patient Centres and Private Practitioners

The Board hardly conceals a certain disappointment at the way in which out-patient centres are developing. The number of such centres under the Mental Treatment Act in England and Wales is 167, a slight gain on the year, but the Board feels that there is still ground for criticism in that many of the centres are mainly diagnostic in character. The value of early diagnosis is not minimized, but it is felt that more continued treatment of those mental disorders which do not necessitate institutional care might be afforded. The difficulty is the insufficiency of staff. "If centres continue to be staffed insufficiently by doctors who have to give up (as many do) part of their leisure to out-patient work, there can be little hope of improvement in this direction."

The Board has emphasized in former years the importance of associating mental hospital staffs with the out-patient centres, but it points out that this does not mean that the centres must necessarily be staffed by whole-time doctors. The instance of St. Albans Clinic is quoted, where psychotherapists in outside practice have been employed, and the Board suggests that this system is one which might well be tried elsewhere. One argument in its favour is that it would give suitable practitioners a chance to establish themselves in private practice in this branch of medicine—a difficult thing to do outside London.

Higher Posts in Mental Hospitals

Another criticism which the Board makes is with regard to the tendency to fix at an unduly low level the upper age limit for appointment of superintendents of mental hospitals. In one case the upper age limit was 40, a condition which must restrict the field of selection.

"We do not undervalue the energy and enterprise of youth, but we feel that appointments involving the care of large numbers of sick persons, to say nothing of the control of mixed staffs often running into hundreds, call for experience and a knowledge of the world which few can acquire without a reasonably long training as a second-in-command. If it is true that most people learn mainly by making mistakes, it is at least equally true that the mistakes made by a deputy can usually be corrected, while the mistakes of a superintendent seldom can be without at any rate a disastrous loss of prestige. Moreover, these premature promotions mean that the top post may remain in the same hands for a longer period than is, in general, desirable. . . . We are opposed to a system which determines success or failure before a man has reached the middle of his medical career."

This is said particularly in connexion with the appointment of medical superintendents, but there are intermediate appointments to which the same principle applies.

The reluctance of some authorities to appoint a medical superintendent at an early stage in the development of a mental deficiency colony is also regretted by the Board. Apart from the need for expert advice in organization and the planning of extensions, there are many ways in which a growing colony needs a medical head. It is admitted that there may be occasional exceptions, but a non-medical administrator, even with nursing experience, cannot be expected to organize the daily treatment of patients and to direct the staff in a colony of 300 or 400 patients of both sexes.

"Success or failure in the future depends largely upon creating a sound organization and a good tradition. To postpone the appointment of a medical superintendent until the necessity for one can no longer be ignored may appear to be an economy, but it is the kind of economy which, in the long run, is apt to prove very expensive."

No visiting medical officer can have the same knowledge of patients as a resident who has them under constant observation.

Mental Deficiency

The statistics of mental deficiency, interesting and abundant as they are, throw no clear light on the prevalence of such deficiency, nor do they allow comparison of one area of the country with another. High figures may merely mean unusual activity on the part of the authorities. The figures do vary remarkably with areas. Take the two areas at the top of the list—the county of Cardigan with 7.69 reported defectives per 1,000 of the population, and the county borough of Walsall with 7.09. Cardigan has ascertained as subject to be dealt with only 1.27 per 1,000, and has actually placed in institutions or under community care only 0.25, while Walsall has ascertained 4.77 per 1,000 and placed 4.34. The lowest proportion reported in any area (1.9 per 1,000) is in West Hartlepool: the local authority has ascertained them all as subject to be dealt with, and has placed in care 0.83 per 1,000. In only a few cases do the numbers in institutional or community care closely approximate to the number ascertained; one instance is Bradford, where 3 per 1,000 of the population have been ascertained and 2.99 placed. Ascertainment, as the Board points out, is undoubtedly the first step, but it may be a useless one unless followed by the provision of care and training both in colonies and in the community—that is, under licence, guardianship, or statutory supervision.

Prominence has been given to the whole subject of the community care of defectives by a law case in Lancashire relating to a patient who was granted licence under the Mental Deficiency Acts. The Board in its report deals extensively with the considerations which should be borne in mind and the steps which should be taken before patients are sent out on licence. The advantage of licence over other forms of community care during the critical years of transition from an institution to life in an outside community lies chiefly in its elasticity and lack of formality. It is intended that it should provide supervision and practical help for defectives, and the power of quick action retained by the superintendent of the institution makes it a safe and favourable form of family care during the years of trial. The number of defectives on licence, under guardianship, and under statutory supervision is 70,500, or 56.2 per cent. of the whole number of known defectives.

At the beginning of the present year close upon 122,000 defectives, whether subject to be dealt with or not, had been reported to local authorities, an increase of 4,830 over the previous year's figure, and almost exactly double the figure of ten years ago.

A.R.P. in Mental Institutions

The Board receives numerous inquiries as to what air raid precautions ought to be adopted in mental hospitals and mental deficiency institutions. While it is difficult to believe that the most vindictive enemy would deliberately bomb a mental hospital, such hospitals are large and imposing buildings and might be mistaken for objects of military importance. In one hospital a protective scheme has been devised and air raid drill practised with success. Patients of the better types have shown an intelligent interest in the drills, have learned how to use gas masks, and some of them have acted as wardens. One report suggests that panic is less probable among the mentally sick than among the general population.

Not often does the Board receive from a patient what it can describe as an eminently sensible suggestion, but one such has been received this year from a patient at Claybury, that visiting chiropropodists might with advantage be employed in mental hospitals.

The Board sent two of its commissioners (Dr. Rees Thomas and Dr. Isabel Wilson) to Budapest, Vienna, and Frankfurt to study the technique of the cardiazol treatment of schizophrenia. Without making extravagant claims either for this treatment or for treatment by insulin shock, the Board feels that it is most encouraging that at last a determined effort has been made to devise some active treatment for a form of mental disorder which has hitherto proved so intractable. Even if it be true that some of the recoveries might have been effected by the older methods, the speeding up of recovery under these new treatments is a great advantage.

At the end of the report the Board hands the British citizen the bill. The total net cost of mental hospitals, including loan charges, is £9,253,528, and of certified mental deficiency institutions £1,348,846, in both cases an average of about 27s. or 28s. a week for each patient.

A report on the use of celluloid in the manufacture of toys, fancy goods, and other articles (Cmd. 5790: Stationery Office, 9d. net) has been issued by the Departmental Committee appointed by the Home Secretary a year ago. It is recommended that the use of celluloid as a component of combs, cuffs, collars, shirt fronts, and hair ornaments should be prohibited. The report also draws attention to the illicit trade in inflammable film known as "junk," and suggests that its sale or hire should be prohibited. Any celluloid articles such as dolls, combs, and similar articles which are at present on sale should be clearly and conspicuously marked "celluloid."

Reports of Societies

THE FEMORAL NECK IN CHILDHOOD

In the Section of Orthopaedics of the Royal Society of Medicine on November 1 Mr. ROBERT OLLERENSHAW delivered his presidential address on "The Femoral Neck in Childhood." During the whole of life, he said, the femoral neck was a vulnerable structure, but at no period was it more subject to various pathological changes than in infancy and adolescence. He gave a long list of these changes, but concentrated on two of them—namely, that type of coxa vara which, for want of a more scientific name, was called infantile coxa vara, and "slipped" upper epiphysis.

Infantile Coxa Vara

Mr. Ollerenshaw's personal cases numbered sixteen in all, ten of them bilateral and six unilateral. The average age of the group was 6 years. The clinical signs were a rolling gait, lordosis, raising of trochanters, loss of abduction, and complete absence of pain. A striking feature in all his patients was their smallness of stature. With regard to aetiology, there appeared to be no hereditary influence, there was an absence of any history of trauma, and there were no signs of rickets. The pathological changes were those of an aseptic necrosis, followed by regeneration of bone. He had found no changes in the blood calcium and blood phosphorus. The condition in its very earliest stages presented small areas of rarefaction in the femoral neck, increasing rapidly in size, and coalescing to form the area usually found when these patients were first examined. The condition became rapidly worse, and eventually, if not treated surgically, ended with the head of the femur several inches below its normal position, with almost no femoral neck at all, complete inability to abduct, and an extremely difficult gait. Treatment consisted of a wedge osteotomy, the wedge being sufficiently wide at its base to allow the femoral neck and shaft of the femur to come into line. This necessitated a very wide abduction, and unless this apparently exaggerated abducted position was produced the operation might fail to yield its desired effect. After the osteotomy was done the body weight was carried almost vertically through the femoral neck, and not across it as before. The neck then became changed in character and developed into a real bony structure.

"Slipped" Epiphysis

Turning to his second group of cases, those of "slipped" upper epiphysis of the femur, Mr. Ollerenshaw said that he had had twenty-two of these. All the patients were between 13 and 16 years of age. Slipping of the upper femoral epiphysis was not the result of trauma, but of disease, and was chiefly concerned with endocrine imbalance. The very large proportion of cases exhibiting definite disturbance pointed quite clearly to the underlying cause. It was clearly established by experiment that trauma to the upper end of the femur would not produce a clean separation of the normal epiphysis. The traumata which were often reported in cases of slipped epiphysis were too trivial to produce even a fracture of the femoral neck, let alone to separate the epiphysis. In the case of a diseased epiphyseal line, however, the normal body weight alone was enough to cause a slip. His patients, with two exceptions, were "heavy" children, eleven of them being of the adiposo-genitalis type.

Most anatomical textbooks put the age of union of the upper epiphysis at 18 years. He believed it was actually considerably earlier, probably from 14 to 16 years. In his opinion repair of a slipped epiphysis took place by

bone. He said this for two reasons: (1) he believed there was no recorded case of a slipped epiphysis giving way for a second time after it had once been united; and (2) in a case upon which, because of gross displacement, he had to operate he observed that the two separated surfaces contained bony elements.

If these children could be caught in the pre-slipping stage—a period in which there were complaints of occasional aching or limping—they should be immediately fixed in plaster and all weight-bearing prevented for three months, followed by calliper for six months. The opposite hip must be carefully examined and regarded with suspicion. In no case had Mr. Ollerenshaw observed definite pre-slipping changes which could be demonstrated radiographically. He had followed two lines of treatment. For those in which the slipping had recently occurred he did replacement under anaesthesia and fixation in plaster. Other cases, which were of some weeks' standing, and in which manipulative treatment could not be effected, he treated by subtrochanteric osteotomy, and abducted the limb sufficiently to reproduce the normal angle of the neck. These cases were given the same period of prevention of weight-bearing as the first group. The cases in which osteotomy was done were undoubtedly functionally satisfactory, but, of course, a little shortened. Manipulation and replacement in the normal position of neck and epiphysis, followed by plaster fixation for three months and subsequent prevention of weight-bearing for a further six months, might be relied upon to produce a very large proportion of good results.

HAEMOLYTIC STREPTOCOCCAL INFECTIONS IN RELATION TO NOSE AND THROAT

The annual Semon Lecture under the auspices of the Section of Laryngology of the Royal Society of Medicine was given on November 3 by Mr. W. M. MOLLISON, whose general subject was "The Laryngologist's Debt to Research." Mr. Mollison quoted from McBride, who delivered the first lecture, to the effect that most of Semon's writings touched on the borderland between general medicine and laryngology, and said that it was that borderland which he proposed to explore. His exploration, however, was devoted to only one sector—namely, acute infections with the haemolytic streptococcus in the origin of which the throat and nose played such an unenviable part.

Mr. Mollison said that haemolytic streptococci were found more often in carriers than in cases of acute infection. No other organism showed so high a disproportion between carriers and disease. D. Colebrook had proved that the nose was far less to blame than the throat. Of fifty-seven cases swabbed, only three had the haemolytic streptococcus in the nose and not in the throat, and in a series of 500 swabbings of the nose and tonsils of doctors, nurses, and attendants (on parturient women) in only 5.4 per cent. were haemolytic streptococci found in the nose, while in 20.3 per cent. they were present in the throat. As the presence of the haemolytic streptococcus was so frequent—one in seventeen of the population carried it—what prevented them all from contracting or taking the infection?

Factors concerned in Resistance

Two groups of factors were concerned in resistance—namely, blood and tissue resistance, which he would not consider, and secondary factors, general and local: the first category included age, sex, nutrition, avitaminosis, fatigue, climate, associated and subsidiary infections, crowding, and the carrier rate; and the second category, the skin and mucous membrane, tonsils, mucus in the nose, and organisms in the throat. Among these local

factors he dealt particularly with the tonsils, which, though a splendid barrier against infection, did sometimes fail and become a focus. When the tonsils were attacked by an overpowering infection they might become an active source of general infection, and their removal, even in the acute illness, might then be advisable.

It was probable that the presence of haemolytic streptococcus in the throat made it less likely that the host would suffer from acute tonsillitis. It was common knowledge that doctors and nurses were open to infections on returning to work after a holiday during which they lost their immunity and presumably their streptococcus. Fever-hospital nurses during their first weeks of service were susceptible to streptococcal tonsillitis, but as they became passively immunized the incidence of cases fell sharply.

There were two principal causes for the origin of infection by the haemolytic streptococcus, one of them milk (not in the province of the laryngologist, except that infection of milk might arise from throat infections in those handling it), and the other an infected person, a so-called contact. Infection originated from a contact or carrier directly, indirectly through a third person, or by droplet infection, this last being the most frequent method of spread. Infection could also be carried in dust, and also, rarely, be air-borne. The lecturer mentioned experiments which suggested that the haemolytic streptococcus could survive for as long as ten weeks in dust.

Prevention of Infection

On the subject of prevention Mr. Mollison said that, not unnaturally, the prevention of cross-infection had exercised the minds of all those in charge of hospitals. As the type of infection never changed among cases of the same type in a ward it followed that they could safely be nursed together. Patients nursed in cubicles only acquired fresh infections introduced by nurses or maids. A sister with even a slight cold could introduce a fresh type, and to prevent this efficient masking should always be practised. The fact that cubicle nursing gave a high degree of protection was emphasized by the following instance: of 167 children suffering from measles nursed in an ordinary ward of twenty-six beds—not crowded—twenty-three died—that is, 14 per cent.; while of 150 nursed in isolation wards only six died—that is, 4 per cent.

Ideally each patient should be isolated in a cubicle and the utmost care be exercised to prevent the introduction of infection by those entering. Alternatively, the exact bacteriological grouping of the infective streptococci in the throats of all persons admitted to hospital should be carried out, and those with the same group nursed together. Both these plans presented considerable difficulties. Actually the method generally in use was so-called bed isolation. It had been found that in the prevention of cross-infection the distance between cot or bed heads was more important than air space per bed.

The Common Cold

Mr. Mollison added a few words on the common cold. The adult carrier was a menace to children, but adequate masking had been shown to be effective in preventing catarrhal infections. As a result of masking of nurses and doctors enteritis (due to catarrhal infection) could be eliminated from children's wards. As an illustration of the extreme difficulty of preventing infection by the virus of the common cold, he mentioned that an infected person prepared food for chimpanzees, which are susceptible to colds, and in spite of very careful antiseptic precautions on the part of those who distributed the food the animals became severely infected.

Laryngologists might think (said Mr. Mollison in conclusion) that bacteriologists took too jaundiced a view, but the tragedy of death from septicæmia after a simple "clean" operation, or after a straightforward removal of

tonsils and adenoids, or after a normal childbirth could not be minimized, and must convince everyone of the vital importance of making a wide search to discover and eliminate the infecting streptococcus. There were, nevertheless, some who felt that the risk of infection from the streptococcus in the normal throat was very remote; they would rely on local examination by an expert to decide if there was any inflammation in the throat and nose, as the risk of infection was then much enhanced. This seemed to be placing a great responsibility on the laryngologist, and one which many would be reluctant to shoulder. What was a "clinically" normal throat? Every laryngologist knew how impossible it was to say that the tonsils were not an infecting focus. The only rational conclusion to be drawn was that bacteriologists must be the final arbiters.

CROHN'S DISEASE

At a meeting of the Devon and Exeter Medico-Chirurgical Society on October 27 Dr. A. AUSTIN EAGGER read a paper on Crohn's disease.

Dr. Eagger said that the condition was described first by Combs and Saunders (1813) and later by Abercrombie (1828). Brann and Le Dentu (1909) called attention to non-specific inflammatory tumours of the intestine. Moschowitz and Willensky (1924) described four cases, in three of which the caecum and ascending colon were affected; in the fourth case the splenic flexure was involved. Crohn and others (1932) defined the condition as a regional ileitis, "a disease affecting the terminal ileum of young adults and characterized by subacute or chronic necrosis with scarring and ulceration of the mucosa, accompanied by exuberant fibrosis leading to stenosis or fistula formation." Diarrhoea was always present. Later reports by Edermann and Burt, Harris Bell and Brun (1933), Jackman (1934), Erb and Farmer (1935), Mayer and Rosi (1936), and others showed that Crohn's original definition needed some modification. Cases had been noted at ages ranging from 2 to 60; diarrhoea was an inconstant feature; and regions of the intestinal tract other than the ileum might be affected.

Four Clinical Types

Four clinical types were now recognized: (1) acute cases with signs of intra-abdominal inflammation; (2) cases with symptoms of ulcerative enteritis; (3) cases with stenosis and symptoms of chronic obstruction; and (4) cases with persistent external or internal intestinal fistulae. The stenotic type seemed to be the commonest. The acute type might resolve or develop into one of the other three types. In the ulcerative type there was a history of diarrhoea with loose offensive stools, which might contain pus, blood, or mucus, accompanied by attacks of colicky abdominal pain, nausea, loss of weight, and mild pyrexia. A tender mass was typically to be felt in the right lower quadrant of the abdomen and there was a mild leucocytosis with marked secondary anaemia. Stenotic cases show the symptoms of partial obstruction and a tumour was sometimes palpable. In the fourth group the usual history was that of fistulae appearing and persisting after appendicectomy for supposed appendicitis.

The aetiology of the disease was uncertain. Erb, in his cases, recovered a coliform organism from the mesenteric glands, liver, and gall-bladder. Relphs suggested that the inflammation occurred in response to a low-grade infection, possibly conveyed by foreign bodies. Mailer had found a streptococcus of the *viridans* group in the blood stream in some cases. Differential diagnosis was difficult: in the acute cases, from bacillary dysentery and appendicitis; in the chronic, from malignant disease, the specific inflammations, ulcerative colitis, tuberculosis, Hodgkin's disease, and actinomycosis. Hourly radiological examinations after the administration of a barium

enema might enable the diagnosis to be made. Kantor stated that loss of segmentation and peristalsis in the lower ileum gave early radiological evidence of the disease. Later, filling defects in the terminal ileum appeared and the so-called "string sign"—a thin irregular streak of barium connecting the dilated ileum above to the caecum below—was characteristic if present. If the condition did not resolve spontaneously it progressed steadily and ended fatally if not surgically treated.

Case Report

Dr. Eagger described a case under his own care. The patient, an unmarried woman aged 43, had had jaundice fifteen years before and frequent attacks of vague abdominal pain ever since. In January last she had an acute attack of lower abdominal pain, accompanied by rigors, pyrexia, and vomiting, and followed by persistent mild constipation. When Dr. Eagger first saw her, on April 17, she had a furred tongue, a normal temperature, and a pulse rate of 80. There was tenderness and rigidity two inches below and to the left of the umbilicus. A radiological examination of the alimentary tract three days later was negative. A catheter specimen of urine examined on May 10 was normal, but four days later she had an acute attack of pain followed by haematuria. A specimen of urine collected the following day contained pus, red cells, and staphylococci. There was a polymorphonuclear leucocytosis, and a left retrograde pyelogram revealed no abnormality. An intravenous pyelogram a week later was normal and so was a catheter specimen of urine collected on May 24. Throughout this period there was marked wasting, weakness, anorexia, and depression. On May 25 visible peristalsis was observed. Laparotomy by Mr. A. L. Candler five days later revealed in the mid-portion of the ileum a tumour-like mass about eight inches long, which was densely thickened and reddish purple in colour. The mesentery was thickened and the glands enlarged. The affected gut was resected and a lateral anastomosis performed. Recovery was uneventful.

Dr. W. A. Robb examined the resected portion and reported as follows: "The specimen consisted of ten inches of small intestine (ileum). The proximal two inches were dilated and showed a moderate degree of hypertrophy. The subsequent seven inches showed a very dense infiltrative hypertrophy with increasing stenosis of the lumen, which would barely admit a quill pen. The mucosa appeared to be covered with a yellow slough. The mesentery associated with the hypertrophied area was also densely thickened and appeared to consist largely of fibrous tissue. Microscopically the lesion appears to be subacute inflammation affecting the mucosa, submucosa, and muscular layers, and the subperitoneal tissue. There are numerous lymphocytes, plasma cells, fibroblasts, polymorphonuclears, and eosinophils, together with a few giant cells. Histologically the picture is that of regional ileitis."

At the same meeting Dr. FRANK ROPER discussed the association between polycystic renal disease and cerebral "berry" aneurysms and described an illustrative case.

SERIAL RADIOGRAPHY IN CHEST DISEASE

At the opening meeting of the North-Western Tuberculosis Society at Manchester Dr. G. JESSEL, in his presidential address on serial radiography in pulmonary disease, said that radiology was the most important single factor in the diagnosis of pulmonary disease as it enabled an accurate diagnosis to be made earlier than was usually possible by clinical methods alone. Fortunately the provision made for x-ray examination throughout the country was steadily increasing. Serial radiography, by which was meant the taking of two or more radiographs of the same patient at one time or at intervals, was desirable both in diagnosis and in treatment. As regards diagnosis the initial antero-posterior radiograph was frequently inadequate, and further radiographs could be usefully taken in oblique, lordotic, or lateral positions. Again, it might be necessary to take

another radiograph after a short interval of time, when the appearances might be entirely different—for example, in inflammatory conditions, and particularly in the pneumonias. Stereoscopic films were a form of serial radiography, but had the disadvantage that they were expensive as a routine procedure. The tomograph also was able to provide useful series of radiographs illustrating the condition at various distances behind the sternum.

Turning to treatment, Dr. Jessel said that whenever any form of special treatment was attempted a series of radiographs was essential, especially in artificial pneumothorax. Whenever other forms of treatment were used—for example, gold or cadmium—serial radiography enabled the progress of the case to be followed. As Wingfield had shown, the direct spread of a temporary quiescent tuberculous lesion in the lungs could frequently be detected only through serial x-ray investigation. In chronic pulmonary tuberculosis the physical signs were often vague and indefinite, and routine radiography at intervals enabled the progress of a patient to be watched and his condition assessed. In this way the pathological changes associated with tuberculosis—for example, fibrosis and calcification—could be followed. In dispensary and private practice a comparison of radiographs taken before and after treatment gave useful information and provided a permanent record.

The cost of serial radiography might be urged as a serious objection, but where x-ray facilities were available it was economical, within limits, to make full use of the apparatus, and the information thereby obtained was well worth the money expended.

The inaugural meeting of the Midland Medical Society took place on October 26 at the Midland Hotel, Birmingham, under the presidency of Professor SEYMOUR BARLING. After a dinner, which was attended by over seventy members and guests, the inaugural address was delivered by Sir JOHN FRASER. His subject was the history of the circulation. He gave credit to Servetus, who first described the pulmonary circulation. Harvey's experiments on veins and their valves were described, and the lecturer concluded his address by a summary of modern knowledge of the treatment of circulatory disease. Professor LEONARD GAMGEE, in proposing a vote of thanks, pointed out that William Withering, who introduced digitalis, was a physician in Birmingham.

The Midland Mental Pathological Society held its ninth general meeting in the New Medical School of the Birmingham University on November 3. Professor H. H. Woollard, M.D., F.R.S., of University College, London, gave a paper illustrated by lantern slides on "The Innervation of Blood Vessels." He dealt with the origin and course of sympathetic fibres to the arteries and arterioles in the limb; nerve fibres were also illustrated having a probable relation to the nocifensor system and to muscular pain. Professors R. D. Lockhart and H. P. Gilding, Mr. F. R. Stammers, F.R.C.S., and Drs. T. C. Graves and F. A. Pickworth took part in the discussion which followed. There was an appreciative audience of twenty-five members and forty-two visitors.

The sixteenth Voyage de Noël on the French Riviera will extend from December 26, 1938, to January 1, 1939. The cost of this six-days tour is 1,500 francs, and the itinerary may be obtained from the Federation of the Health Resorts of France, the English office of which is at B.M.A. House (North Wing), Tavistock Square, W.C.1. This charge is exclusive of the journeys between England and Cannes, where the tour will start: places to be visited include Antibes, Grasse, Vence, Cap Martin, Monaco, and Nice.

ENGLAND AND WALES

Great Ormond Street Hospital for Sick Children

The recent opening by the King and Queen of the rebuilt and reconstructed Children's Hospital recalls that this institution was the first and for some years the only children's hospital in the United Kingdom, serving as a model for the other children's hospitals subsequently established. The new building has risen chiefly on the site of the former garden. It has seven stories constructed to accommodate 326 patients, including wards for thirty-six private patients, three operating theatres, and various laboratories, kitchens, and the other departments required by a modern hospital. What is left of the old hospital is at present housing the out-patient department, which is now also being reconstructed. The eighty-sixth annual report of the Board of Management covers the calendar year 1937, and a short history of the hospital can be obtained from the secretary. Generous response to the rebuilding fund appeal has enabled the progress of the work to be accelerated, but it is announced that a further £250,000 is still required. In spite of the work of reconstruction the number of in-patients treated during 1937 exceeded that in 1936. The weekly average cost of in-patients increased somewhat, mainly owing to improvements in the dietary and the higher cost of surgical and dispensary supplies. The figures for the branch hospital at Tadworth Court were much the same as in the previous year, the work of the recovery section and the convalescent pavilion permitting continuity of treatment and medical research which would otherwise have been unobtainable. All appointments to the honorary and salaried medical staffs are now equally available to men and women. Although a larger staff is now employed, no additional expense has been incurred, thanks to the adoption of a new scheme suggested by the medical committee. In the medical report it is remarked that the appointment two years ago of a resident anaesthetic registrar has secured the keeping of accurate records of this important section of hospital work. Last year nearly 8,000 general anaesthetics were administered, and premedication has proved of great value in this connexion: of the patients receiving an anaesthetic in the in-patient department approximately one-third were relieved of all apprehension by this modern procedure. Prolonged desensitization against asthma was found to render the attacks less frequent and milder, though it did not prevent their occurrence. A new protective serum against scarlet fever was tried in one of the surgical wards with great success, the amount of injected material being very much smaller than any hitherto used. There was a great decrease in the number of children attending the department for venereal diseases, and since such a decline has been reported all over the country it is obvious that the intensive work in such clinics in past years has yielded valuable results and that these diseases are being controlled.

Birmingham Health Report

The report for 1937 of the medical officer of health for the City of Birmingham records a slight rise in the death rate, largely owing to the prevalence of influenzal conditions in the spring. On the other hand, the infant mortality at sixty per thousand has never been lower in the city, although equalled in 1930, while the maternal mortality also shows a gratifying reduction, especially satisfactory as evidencing a diminution in septic conditions in child-birth. The Birmingham birth rate shows a slight rise for the fourth year in succession, but this coincides with the highest illegitimate birth rate for ten years, attributable, so the report suggests, to the more general use of contraceptives regarded as certain preventives of the result

of licence. During the year under review a municipal salaried midwifery service was established in accordance with the requirements of the Midwives Act, 1936. Following a number of compulsory and voluntary retirements the midwives available for the city at the end of the year totalled 158. Of these ninety-nine were city midwives, forty-seven independent, and twelve working under the Maternity and Queen's Hospitals. The emergency service for the domiciliary treatment of obstetric shock and haemorrhage was used for eight cases during 1937. All these patients recovered, and the consultants concerned expressed favourable opinions of the value of this service. Under the Public Health Committee's scheme general practitioners called in consultants for eighty-one obstetric and twenty-six puerperal cases.

SCOTLAND

Hospital Co-operation

In an address at the opening recently at Girvan of the annual Congress of the Royal Sanitary Association of Scotland, Dr. James M. Mackintosh, Chief Medical Officer of the Department of Health for Scotland, emphasized the necessity for co-operation between the voluntary and the statutory hospitals. He said that 1938 marked an important centenary in public health; before 1838 no Act of direct sanitary intention had been placed on the Statute Book. The increased interest in public health stood out as a feature of progress in the twentieth century. But the full implications of the modern doctrine of personal health had not yet been realized. Physical fitness alone was a barren ideal, and must be linked with some idea of what was to be done with the body when it was made fit. A re-examination of the whole educational system was necessary with a view to giving health education a central place. No scheme of medical services could be successful until there was a complete working arrangement between the voluntary and the statutory hospitals. With a wise use of existing resources the inadequacy of hospital accommodation would be relatively small. The principle of regional co-operation had been tried with considerable success in Aberdeen, and there was evidence of tentative schemes elsewhere. Co-operation had failed not because of lack of money or opportunity but because of lack of faith. There was a hesitation to take the necessary action because it would interfere with long-established practices.

On the second day of the congress, Dr. W. G. Clark, medical officer of health for Edinburgh, dealt with some aspects of public health policy. Regionalization, he said, was an important matter at the present time, for local public health organizations were generally too small to deal with exceptional circumstances such as outbreaks of infectious disease. When public health measures were regionally administered, consulting staffs were available, large hospitals of 400 to 500 beds were more economically equipped, and in the event of an epidemic the whole resources of the region were at the disposal of the locality involved. Such schemes could only be carried out when a large centre was included, and it was doubtful if any area of less than 100,000 population could afford to maintain what was now regarded as a complete health service. With regard to infectious disease, he urged that a central register of carriers should be prepared and kept by the Department of Health.

Hospital Extensions

At the opening of an extension to Galashiels Hospital, which has cost £25,000, Sir John Fraser of Edinburgh University said that voluntary hospitals were encountering difficulties in obtaining sufficient money to maintain the usual standard of efficiency and at the same time to make necessary extensions. The problem of hospital adminis-

tration had been discussed for several generations. The treatment of patients in small country hospitals not only relieved suffering locally but afforded opportunity for a corresponding number of patients to be treated in the hospitals of the larger centres. The importance of this type of assistance was not sufficiently recognized, and if it could be made more general it would go far to solve difficulties of the larger hospitals. Illness was often more easily borne in the quietness of a country town than in a big city, and he believed that this factor would be increasingly taken into consideration in the hospitals of the future. The extension provides a new wing with a public ward and several private rooms, and in addition there is a new operating theatre, laundry, and kitchen, and an up-to-date x-ray installation. The hospital, which previously accommodated fourteen patients, has now thirty-one beds.

An auxiliary hospital to the Dumfries and Galloway Royal Infirmary, which has been provided at a cost of £18,000, was opened by the Earl and Countess of Mansfield on November 3. The Earl of Mansfield explained that this addition, the Grove Convalescent Home, would provide accommodation for fifty-five patients, and that the directors also contemplated an extension to the infirmary, but there had been delay in the latter scheme owing to negotiations with local authorities, who desired to reserve for their own needs some seventy beds in the institution.

Correspondence

Treatment of G.P.I.

SIR,—Dr. B. H. Shaw's letter in your issue of October 29 (p. 917) quotes some figures purporting to show the results of different methods of fever therapy in G.P.I. Statistical evidence readily lends itself to misinterpretation. I would stress the fact that clinical recovery is not an accurate criterion of the efficacy of any type of treatment. It seems unlikely, having regard to the histopathology of the disease, that therapy does more than destroy the syphilitic infection whereby, although inflammatory changes may resolve, degenerative changes persist. Thus the resultant clinical picture will depend on the degree of degeneration present before treatment is begun. Investigations carried out here have led us to the conclusion that the production of a normal cerebrospinal fluid is a more reliable gauge of the success of treatment than that of "clinical recovery." As regards the recovery figures quoted, it should be pointed out that the Board of Control figures relate to mental hospital admissions, many of the patients being already far advanced cases, whereas Neymann's figures refer to general hospitals as well as mental hospitals.

Regarding the mortality rate of malaria therapy, I would like to quote from the records of patients treated here between June, 1937, and June, 1938; this time period was selected purely at random, and may therefore be regarded as a sample of our general results. During this time 107 men and fifty-six women were admitted suffering from G.P.I., and of these 100 men and forty-five women were treated by malaria. Among the women no deaths occurred either during the course of malaria or within a few weeks after; of the men three deaths could be directly attributed to malaria; one of these developed severe cardiac asthma during fever and died from heart failure. At necropsy a plaque was found at the beginning of the left coronary artery, although the aorta itself was relatively healthy and careful examination of the heart

during life revealed no abnormality; seven others died within two to three weeks following termination of malaria. It might therefore be argued that malaria was also responsible for their deaths, but in four the disease was well advanced before therapy was undertaken. Of the remaining three the cause of death was respectively appendix abscess, lobar pneumonia, and generalized boils. This death rate is little if any higher than that quoted by Neymann, and having regard to the very small number of cases left untreated it can on these figures be argued that malaria therapy is as safe as electropyræxia. Of the eighteen untreated cases seven were men, of whom two were treated with tryparsamide—one on account of his age and uncompensated cardiac condition and the second because of his emaciated condition; one died within five days of admission and four within six weeks. Of the eleven women, one died five days after admission, seven within four weeks, and three within three months.

Among cases treated successfully by malaria have been patients with aortic and mitral disease, diabetes, Huntington's chorea, and many cases of syphilitic aortitis.

As the treatment of G.P.I. by electropyræxia is of relatively recent origin, I can hardly agree with Dr. Shaw that "an authoritative comparison with other methods of treatment is *long overdue*." (The italics are mine.) It is not my purpose to decry the value of electropyræxia, but I am convinced that malaria therapy is still one of the most successful therapeutic agents in the treatment of neuro-syphilis and is far from being the 'dangerous' procedure it is implied to be in Dr. Shaw's letter.—I am, etc.,

Horton Hospital, Epsom, Nov. 1.

W. D. NICOL.

Social Pathology

SIR,—Dr. A. J. Brock in his letter to the *Journal* of October 8 (p. 762) raises the question, "Is our nation becoming less healthy?" This is a very important question, because, as Dr. Brock notes, the future existence of the British peoples depends not only on a knowledge of the correct answer but also on action based upon this knowledge. What answer we give depends on the meaning we attach to the word "health." For example, we may consider national health in terms of height, weight, longevity, and freedom from devastating epidemics. Accordingly, when official statistics indicate that people are becoming taller and plumper, are living longer, and are free from severe outbreaks of infectious disease, we assert that the nation is becoming healthier. However, we must not forget that this assertion of improving health is really an inference based on an assumption, the assumption being that the needs of living men and women are exactly comparable to the needs of livestock—namely, suitable food, shelter, air, light, and physical exercise. In the past all "public health" measures and most "social" ones have been based on this essentially veterinary assumption. Indeed, it was inevitable that this should be so, because these needs are so obviously basic ones. Improvement in national livestock health has been effected therefore—at least in part—by a growing knowledge of the nature of these needs and by the application of measures directed against environmental factors which frustrate or deny the fulfilment of these basic animal needs. In practice this has been achieved by "public health" action in respect of impure or inadequate diet, improper housing, defective drainage, insufficient exercise, etc.

There is, however, another way of regarding health, and this is based on a different assumption. It includes the veterinary assumption, but regards it as partial and inadequate.

quate. It states that living men and women have another range of needs—for example, work, work to an end, leadership, a belief that life has a meaning or goal, etc. It also assumes that if these psychological needs are frustrated by environmental factors then the impulses behind them, being denied satisfaction, turn in upon the people and begin to destroy them. (A useful account of this assumption is given by Karl Menninger in his book *Man Against Himself*.) Sometimes the self-destruction is very obvious, as in suicide; sometimes less obvious but just as definite, as in chronic and recurring neurotic illnesses, as well as in many examples of organic sickness labelled by such terms as anaemia, rheumatism, gastritis, peptic ulcer, bronchitis, etc. (psychosomatic illnesses). Also, self-destruction may be manifested in a more remote way, as in the refusal to bring forth children. In other words, a community in which basic psychological needs are frustrated slowly falls sick, disintegrates, and decays. On this assumption statistical facts which reveal disintegration of this nature would be the following: (a) a rising suicide rate; (b) a rising incidence of psychoneurotic and psychosomatic illnesses; (c) a declining birth rate. All three of these trends are shown in our national statistics during recent years.

This second concept of "health" is nearer the proper meaning of the word, which originally referred to wholeness or integration. It also has reference to the ideas of vitality, efficiency, and life more abundantly. The question, "Is the nation becoming less healthy?" can no longer be answered with a vigorous and self-satisfied negative. The indices suggest the possibility of a very different answer. Failure to appreciate the deeper meaning of "health" and the absence of action against environmental factors (including social measures) which frustrate the basic psychological needs of a community will, on this second assumption, result in further disintegration.—I am, etc.,

Glasgow, Nov. 2.

JAMES L. HALLIDAY.

Decline of Breast-feeding

SIR,—The unnecessarily high death rate from enteritis and diarrhoea in babies under 1 year still continues, and Dr. J. C. Spence (October 8, p. 729) is quite right in stressing the fact "that the encouragement of breast-feeding is one of the methods of combating the excessive infant mortality. But there are many who do not recognize it." He goes on to quote from the annual report of a medical officer of health in one of our large towns in which the medical officer advances the astounding proposition that breast-feeding on the whole is not a success, in fact that it is a more frequent cause of dietetic trouble than artificial feeding, and also affirms that he has not seen any evidence that convinces him "that the artificially fed child is more prone to disease or more likely to succumb to disease than his naturally fed brother"; finally, he thinks that the mother is better if she does not feed her child.

Again, some general practitioners in North Kensington formed a medical society with the object of investigating the cause of infant mortality in Kensington. Dr. Horace A. Nathan says (October 29, p. 916) that the following sentences may be quoted from their report: "If it is accepted that environmental conditions can so affect a mother that an infant at birth is lacking in vitamins, it seems likely that breast milk will be similarly lacking. Could a more unsuitable person be found to breast-feed this particular infant?" Of course, there is no shred of evidence to support this hypothesis. If only the doctors

had spent their time and energy in studying the technique of breast-feeding they would have done valuable service in lowering the death rate. During the siege of Paris in 1870 mothers had to feed their babies on breast milk because no other food could be procured for them. The result was that the infant death rate declined considerably, the environmental conditions being anything but ideal.

The views which I have quoted show the direction in which some of the profession are influencing the mothers of our rising generation, and if it were not for the welfare centres, whose main purpose is to encourage breast-feeding in every way, possibly there would be little chance of keeping the death rate from enteritis even at its present level. I agree with Dr. Spence that about 95 per cent. of women can suckle their babies and that only 5 per cent. cannot do so for various physical reasons, but when he says that the mother should choose the times of feeding most suitable to herself and her child I really cannot agree. I should have thought that no one would question the importance of regularity of feeding times, as irregularity in this respect has been such a constant cause of vomiting and diarrhoea.

Thirteen years ago I was asked by the public health authorities to attend cases of enteritis and diarrhoea in their own homes when the mother could not afford medical fees. I have seen 1,500 such cases in their own homes during this period, and the mortality works out at 3.5 per cent. Most of these infants were artificially fed, and the cause of the illness was dietetic. No pathogenic organisms were found in the majority of cases. Outbreaks of Sonne dysentery occurred from time to time, but these were of a mild order, and the children usually were on the way to recovery in five days.

I have seen a considerable number of breast-fed babies with vomiting and diarrhoea. The treatment consisted in stopping the breast milk for twenty-four hours and allowing the baby to take as much water as he wanted. The next day breast-feeding was begun again; the vomiting usually stopped completely, but the diarrhoea continued for a few days and was treated by a bismuth and chalk mixture, three times a day. I never gave any artificial food. Some of these cases were in a good deal of pain, passing blood and mucus in their motions, and the mothers and doctors were anxious to stop the breast milk, but, luckily, they allowed me to pursue my course, and the results were excellent. I have never seen a fatal case of diarrhoea and vomiting in a baby that was being entirely breast-fed, except once in a child of 2 months who died from otitis media. The diarrhoea and vomiting was secondary to this, so that all the deaths in my series of cases occurred in artificially fed infants, except two who died from Sonne dysentery.

Over-feeding with breast milk, apart from attacks of diarrhoea and vomiting, has no disastrous effects such as one sees in artificially fed infants; it can be rectified by increasing the intervals between the feeds and only allowing the child to suck for three to five minutes at a time. I have seen infants put on weight in a satisfactory manner and remain satisfied on only three or four feeds in the twenty-four hours. The trouble arises when there is not enough breast milk; this may only be a temporary condition, but the error is often made of giving a bottle alternately with the breast, so that the child has three breast-feeds and three bottle-feeds in the day. This practice is wrong because the quantity of breast milk is sure to diminish owing to the lack of that stimulation which suction gives to the breast. A far better method is to give a complementary feed directly after the breast-feed and to give the artificial food with a spoon out of a cup instead of filling a bottle. After a week or two of this treatment the breast milk will often increase in quantity, so that the complementary feeds can be discontinued. I have often brought back the breast milk after the infant has ceased suckling for five weeks in cases in which the child was doing badly on artificial food. It only requires perseverance, and is always worth while provided one can squeeze a drop of milk from the nipple. In cases of mammary abscess in one breast the infant can be fed perfectly well on the other side.

I have only indicated some of the common difficulties in the technique of breast-feeding. I believe the importance of education is not sufficiently recognized, and under these conditions it is very alarming to see in a recent order of the Ministry of Health that panel practitioners attending postgraduate classes are not to receive instruction in diseases of infancy or childhood. Surely, in large towns among the poor and overcrowded population an up-to-date knowledge of the diseases of infancy and childhood is the most important branch of medicine for the general practitioner to study. I sincerely hope that the Ministry will reconsider its decision.—I am, etc.,

Kensington, Nov. 5.

RONALD CARTER.

Prognosis of Anxiety States

SIR,—It would appear that Dr. Arthur Harris does not appreciate the significance of the criticism that has been made of his article on the prognosis of anxiety states (*Journal*, September 24). He set out to estimate the factors of prognostic importance in a follow-up of 123 cases (this was one of the stated objects of the investigation), but completely excluded the question of treatment. I pointed out that this was a curious procedure, and indicated that it rendered his results of little value. In your issue of November 5 (p. 966), however, Dr. Harris attempts to justify the omission on the singular ground that he "could not determine accurately how much and what type of treatment each case had received," and from other remarks he makes it is evident that the patients had received very different forms of treatment.

In effect, therefore, Dr. Harris has, evidently unintentionally, provided the answer to the question I put in my previous letter as to whether he considers that treatment is to be regarded as significant in estimating the prognosis in anxiety states, and his answer is in the negative. This may conceivably be true, but is it what he meant to imply?—I am, etc.,

London, W.1, Nov. 7.

FREDERICK DILLON.

Thimble for the Surgeon

SIR,—Mr. Dickson Wright emphasizes justly the importance of Mr. T. E. Coulson's clinical memorandum in your issue of October 15. The use of a thimble to guard the finger when making a stab incision is a valuable device, especially in cases of acute peritonitis, and I am surprised to learn from Mr. Dickson Wright's letter that more use is not made of it, in spite of Sir William Wheeler's writings on the subject. Some surgeons, of course, disdain such adventitious aid and cut down boldly into the hollow of a cup made by the hand and fingers, but such a manœuvre presupposes an original incision which will admit the whole hand.

For some years I have used a finger shield made by Messrs. Down Bros. for the late Mr. C. P. Childe of Portsmouth.

"The instrument allows free flexion of the finger. When used inside the abdomen, the forefinger encased in the finger shield, and the mid-finger, are inserted together. The latter feels that nothing is in the way, and the guarded finger is then cut down upon at once with a single stroke of the knife."

Personally I have found it more convenient to wear the shield on the mid-finger with a finger on either side to protect the viscera. As compared with a thimble, there is less danger of this instrument slipping from the finger, but a thimble is simple, efficient, cheap, and easily procured, and, as Mr. Dickson Wright says, should have its place in every surgeon's kit of instruments.

I am not sure that the suprapubic route to which Mr. Coulson refers is always the best in the treatment of pelvic

abscess. In many such cases the abscess tends to point in the rectum or vagina, and on examination an area of softening will be readily appreciated on the wall of either cavity. Sinus forceps are sufficient to lay open the abscess. Drainage established by this route is dependent, and the abscess cavity closes in quickly. Contrary to what one might expect, the opening in the rectum or vagina heals smoothly. An additional advantage is the avoidance of a tube which traverses the peritoneal cavity.—I am, etc.,

MICHAEL J. SMYTH, M.Ch., F.R.C.S.

London, W.1, Oct. 31.

SIR,—In the *Lancet* of April 10, 1909, Mr. C. P. Childe described a metal finger-guard made by Messrs. Down Bros. for use in making a counter-opening. This guard has been in general use since that time, and it is less likely to slip off and is less clumsy than a thimble. Mr. Childe primarily advocated its use to supersede having to cut down on one's finger or on to an instrument inserted intraperitoneally. The latter method involved the risk of wounding intestinal tissue. The guard was to be worn on the forefinger, and the middle finger could then detect any intestine that was in the way. The thimble method, if preferred, should certainly be used in the same manner.

But there is still an element of danger. On one occasion when using the guard I wounded a piece of collapsed small intestine which had escaped notice on the thumb side. Fortunately I noticed a little bile staining on the bright nickel, and was able to find and hold the gut into the small wound with my thumb and repair it, with no bad result; but I feel sure that if I had been using a thimble I might not only have lost the gut but the thimble also and perhaps the patient.

A safe way is to displace the intestine with the middle finger, press it against the peritoneum, and then slide the guarded finger forwards to this spot before cutting down.—I am, etc.,

London, W.1, Nov. 7.

G. H. COLT.

Septal Deflection

SIR,—I read with interest Mr. W. S. Syme's article on septal deflection in the *Journal* of September 24 (p. 656). At the Annual Meeting at Plymouth the subject was discussed, and I believe Dr. Ritchie Rodger said that the operation of submucous resection of the septum was probably not too often performed. From time to time rhinologists are cautioned against resorting to this operation on inadequate grounds. I am inclined to lean towards Dr. Rodger's point of view, as I believe that the operation will not be performed unnecessarily if the surgeon realizes that it is for the benefit of the patient and not for the benefit of himself. I agree with Mr. Syme that submucous resection of the septum is the favourite operation of some specialists. If it is their favourite operation because they do it so well in indicated cases, then I have no quarrel with them, since it is an operation which must be adequately performed. It can usually be performed once only, and it must therefore be a complete and not a so-called "partial" submucous resection, and special attention must be paid to the upper part of the septum opposite the middle turbinates. A patient on whom a partial submucous resection has been performed to remove an offending spur near the floor of the nasal cavity is as liable to develop frontal sinusitis after the operation as before if a deviation is left high up in the septum. I have on more than one occasion been put to a difficult task in performing an intranasal frontal operation in a case in which the chance of doing a submucous resection has been spoiled by such a partial resection. I believe

that submucous resection should be performed more often during other intranasal manipulations to give better access to the area of operation. If this were done, nasal polyps would be more effectively removed and ethmoidectomy more effectively performed; intranasal frontal operations would give better results; post-operative anterior rhinoscopy would more readily reveal recurrence of disease; and there would be less chance of adhesions after removing or attempting to remove polyps through a narrow nasal cavity.—I am, etc.,

National Hospital, Bloemfontein,
South Africa, Oct. 21.

J. E. THOMSON.

Periodicity of Influenza

SIR,—Recent studies of neoplastic periodicity have shown (*Brit. J. Surg.*, 1938, 26, 113) that in a number of patients the primary or recurrent malignant disease has followed about three weeks after an influenzal attack. In the attempt to collect further instances of this relationship I should be grateful for the help practitioners could afford me by sending me notes from their case-histories or from patients' diaries (1) of the exact dates of recurrent influenzal attacks, and (2) of any instances of malignancy following influenza.

Influenzal periodicity may be studied (1) in epidemics and (2) in individual patients' case-histories. The former has yielded valuable results. Taking the end-of-the-war severe epidemics there were three peaks, in July–August, 1918, in November, 1918, and March, 1919: these illustrate the "half-periods" noted in neoplastic recurrences as possibly due to a double strain; and following each strain in a thirty-three weeks' periodicity we can fit in all the succeeding major and minor epidemics, noting that in the summer months we have similar "missed periods" to those seen often in neoplastic diseases. The present rise was to be expected; the next major epidemics may be expected in February–March of 1939 or 1940, or in February, 1941, or in January, 1942 or 1943, as reference to the table of dates (*loc. cit.* above) shows.

But epidemics from their nature must have considerable variations, and the estimation of the precise periodicity is more likely to be obtained from individual patients' histories: in this way practitioners could render valuable assistance, as more knowledge of the periodicity of influenza would enable accurate predictions to be made of the months when serious epidemics are likely, and patients could take prophylactic measures, with a reduction in both influenzal and cancer mortality.—I am, etc.,

London, W.1, Nov. 5.

J. H. DOUGLAS WEBSTER.

Cure of Colds

SIR,—Dr. J. B. Sherman's article on the prevention of colds (*Journal*, October 29, p. 903) prompts me to mention a method resulting in a quick cure or, one might say, an abortion of a cold. This method might be adopted by surgeons and physicians, and certainly by physiotherapists, for themselves and their families.

The treatment to produce abortion of the cold must be resorted to within the first few hours or at least on the evening of the day on which the cold appears, for then one or two treatments—in my own case one treatment—will result in the drying up of the nasal secretion, the disappearance of the sensation of fullness in the ears, and the vanishing of the husky voice with the production of an almost abnormally dry pharynx. It consists in placing the 6-metre short-wave glass-covered electrodes on each

cheek: the metal electrode is withdrawn, so as to heat the deep tissues more than the skin, and the treatment is applied for ten to fifteen minutes. If one has a proper fear of a cold one has a treatment twice on the first day and, if necessary, on the following day. Elderly patients—even if one avoids the caloric reaction by applying the same heat to each cheek—will feel giddy for five minutes following the treatment, and so must sit still after it.

Incidentally this treatment when repeated is excellent for acute sinusitis, and in the case of subacute sinusitis, when the fear of dissolving the toxins in the nose with water has vanished, it can be combined with the use of Lowndes-Yates suction apparatus.—I am, etc.,

Harrogate, Nov. 1.

W. S. THACKER NEVILLE.

Civil Medical Organization in War

SIR,—If we are to judge by the conversation of many of our colleagues in recent weeks the medical profession as a whole is greatly concerned with the organization of medical services in time of war. It may well be that the Government has a practicable scheme prepared, but with the evidence of general muddle in the past few weeks still fresh in our memories we can be forgiven if we continue to harbour misgivings. The history of the A.R.P. Department of the Home Office is hardly such as to instil confidence.

We wish to draw attention to two large issues in the organization of medical services.

1. In the last war in which we were engaged part of the profession joined the Army while the remainder stayed out of uniform and carried out the necessary attendance on the civilian sick. Such a division of labour was natural and reasonable in warfare as conducted in those days. Unfortunately, however, as we are all aware, the technique of war has changed, and the front line which has now to withstand the brunt of the enemy's fury is to be found in the homes of our civilian population—a front line, incidentally, crowded dangerously with millions of people as yet undisciplined to deal with the expected onslaught of bomb, gas, and fire. We therefore feel that the division of the profession into purely military and civilian components is completely artificial, and can only lead to misdirected energy and ultimate chaos of the medical services. This is particularly true of congested urban areas but, as we shall hope to show later, may well apply to rural districts also. If bombing is sufficiently intensive and continued over fairly lengthy periods (and this we may reasonably expect if the bomber is to achieve the end it has in view) hundreds of so-called civilian doctors in the affected areas will for long periods be engaged in nothing less than military practice—that is, for lengthy periods they will be giving whole-time service to the State and yet not be State servants. No matter how we organize first-aid posts, ambulance services, etc., the family doctor will have to devote himself to hundreds of cases of minor surgery in order to relieve hospitals already congested with the more seriously injured. Further, many elderly doctors with surgical experience in suburban areas may be called upon to relieve the overworked full-time surgeons in the hospitals, in which case the purely civil work to which they had been allotted will be completely neglected and their income from it correspondingly reduced.

2. The second point we wish to stress is the medical implications of large-scale evacuation of population into rural areas. We are led to understand that at least three and a half and perhaps five million people will be evacuated from London, and proportionately

large numbers from the East Coast and the industrial Midlands. In such circumstances we do not think we exaggerate when we estimate that at least six million town dwellers will suddenly find themselves herded into the rural districts of England and Wales. The medical problems involved in this immense shift of population are of a type quite different from those we have already considered; but of at least equal importance in the urgency of their solution. This aspect of the problem was referred to by Professor Major Greenwood in his admirable letter in the *Journal* of October 22 (p. 861), and it is unnecessary to labour the matter; it is clear enough, however, that if large numbers of town children accustomed to what may be termed mechanized sanitation—the turning of taps, pressing of switches, and pulling of plugs—are to be suddenly billeted in farms, cottages, and holiday camps, the closest supervision of water and milk supplies and of sanitation will become an urgent necessity. The earth closet properly used may be beyond reproach, but it easily becomes a menace to health.

Rural water supplies, even in these days, are not always above suspicion, and are frequently uncertain in quantity if not in quality. To ensure such adequate supervision the staffs of the public health departments of those rural sanitary authorities into whose areas immigration is to take place will have to be both strengthened and augmented. For in rural areas the M.O.H. is often a busy general practitioner, able to devote relatively little time to health problems and relying mainly on his sanitary inspector; moreover, the combined post of sanitary inspector and surveyor is even yet not unknown. Another obvious problem is that of the movement of populations from infected areas. It requires no expert knowledge and but little imagination to realize the dangers which will arise if the need for evacuation coincides with an epidemic in a district of typhoid, diphtheria, or influenza. It seems that, at the least, plans for mass immunization against typhoid and diphtheria should be in readiness, and more strenuous efforts might well be made during peace time to get children protected against the latter disease if not against the former. The evacuation of the three thousand Spanish refugee children from Bilbao last year showed on a small scale how successful mass inoculation can be in preventing the dissemination of typhoid from an infected group.

But enough has been said to indicate some problems and dangers which will inevitably arise, and we are at least entitled to ask what steps have been or are being taken to meet them. The problems being so immense, and the civilian and military aspects so intermingled, we feel that organized whole-time service for all doctors, whether civil or military, is essential. If such a State service should be introduced we would urge that some form of local autonomy for the profession should be an integral part of the scheme.—We are, etc.,

L. S. FRY.

L. P. GRAY.

London, E 4, Nov. 1.

SIR.—Mr. R. Ogier Ward in his letter (October 29, p. 914) points out that in any future war the number of dead and wounded would run into many thousands every twenty-four hours. If this is a fact, and I believe under modern war conditions it will be so, whether the large towns are evacuated or not, surely surgeons and doctors will find it absolutely impossible to cope with the work they will be called upon to do. In that case would it not be better to throw all the weight of our profession into the prevention of war rather than to prepare for something which is a physical impossibility?—I am, etc.,

Manchester, Oct. 31.

WINIFRED HALL.

Air Raid Precautions

SIR.—As medical officer of health of a county of a thousand square miles whose war-time population will be some three-quarters of a million, living to a great extent amid very important coal, iron and steel, aeroplane, and munition works, I was under the heavy responsibility of organizing the necessary aid for possible air raid casualties. There were conditions imposed which from the first appeared to me to negative the formulation of a successful scheme. I did not hesitate to argue to the utmost of my power against these conditions with the departments concerned, but without effect. Experience during the crisis has convinced me that I cannot leave it at that. I now feel at liberty to express my beliefs and to make my suggestions to the medical profession. It is not my wish to criticize the past; when I mention it I do so only to show that it is necessary to consider suggestions for the future.

I am unable to understand the Home Office argument that the first-aid posts are not for those requiring medical aid, and that anyway there will not be enough doctors to staff them. The people will expect medical as well as first aid at the posts. I believe that the treatment of casualties outside hospitals cannot be left entirely to medically unqualified first-aid volunteers. I believe that medical aid must be available promptly at every first-aid post: without it a tremendous amount of unnecessary work will be thrown on the nearest hospital, which will be all too fully occupied. I believe that medical aid at the posts will provide that feeling of security without which we must anticipate panic not only among the injured but among the first-aid volunteers, most of whom will have had no previous experience of dealing with casualties. As to there not being sufficient doctors to staff the first-aid posts, the Home Office appears to be under the impression that to provide medical aid at first-aid posts would necessitate doctors being stationed there whether the posts are called upon to function or not. That is not my idea.

There is another matter which should receive the fullest consideration of the profession—I refer to the secret compilation of the services that doctors were prepared to render in war time made by the British Medical Association on behalf of the Committee of Imperial Defence. At no time during the crisis, in spite of repeated and urgent requests, were the British Medical Association permitted to divulge that information, without which it was impossible for medical officers of health to arrange casualty services in their areas. The sooner the magnitude of the medical side of air raid precautions is realized the better, for when it is it will also be appreciated that it cannot be efficiently organized as a last-minute panic improvisation.

The solution to the medical problem is to my mind very clear. The problem is to provide medical aid for casualties occurring among a population at least twenty times as great as that at any time seriously exposed to casualties in the last war. Then nobody suggested that the problem could be efficiently met by a service such as is now suggested—namely, an ill-defined, uncertain, voluntary service, almost parochial in character, without rank, uniform, or disciplinary powers. It is essential that we should build on our past experience. What is obviously required is a civilian counterpart of the R.A.M.C. In short, we require a permanent Air Raid Medical Corps. This corps should be built upon the lines of the Territorial Army. It should be a uniformed corps, with rank, local training depots, and equipment, and a similar system of enlistment, pay, and allowances to that of the Territorial Army. As

this corps would be dealing with casualties among women as well as men the corps should have women as well as men in all its ranks. Selection of recruits should be made with care at least equal to that exercised by the Territorial Army, and the corps must have prior call on the services of its members in war time. The services of members could be required over a defined area. The function of the corps in war time would be to provide for the civil population all medical and ancillary services required inside or outside hospitals. Among other things it would provide a nucleus of trained but non-medical first-aid personnel as a standing crew at each post during war time, and would be expected on short call to provide from the local depots what I might describe as surgical flying squads for posts or hospitals. Space will not permit me to go into further details, but I hope I have given enough to make clear what I suggest is required.—I am, etc.,

Derby, Nov. 1.

W. M. ASH.

SIR,—I should like to add my support to what has been said in your columns by Mr. R. Ogier Ward, Dr. Clement Francis, Mr. J. Johnston Abraham, and Lieutenant-Colonel Cyril Helm on this subject.

There is no doubt that had war come at the end of September last it would have found us woefully unprepared. The magnitude of casualties from high explosive bombs in large towns like London would have been enormous, among both the lay and the medical population. This would have meant that the limited supply of doctors would have been grossly overtaxed and their numbers greatly decimated, so that very soon there would not be sufficient to deal with the casualties as they arose. To fill the existing hospitals in London with casualties and staffs of medical people would be the surest way of sacrificing valuable and useful lives that could be and ought to be preserved.

Surely the first thing to aim at is to reduce the number of casualties to a minimum. No doubt the best way to do this would be to deal with the bombing machine effectively. At present no method is known, though Sir Kingsley Wood says he does not despair of this being done. Until this can be accomplished other methods must be found. It seems to me that the most satisfactory way would be the construction of an elaborate system of bomb-proof shelters on a most extensive scale. Carefully planned, this system could act in war time not only as shelters during air raids but as places of safety for casualties, where medical and surgical attention could be given without interference and risk from raiding aircraft. This would not only ensure that the number of casualties would be comparatively small and able to be dealt with without overtaxing the doctors, but it would create a sense of security and avoid panic. Further, by suitable planning the system could be used to relieve the ever-increasing traffic problem—in both peace and war time—for storage and garaging, and no doubt it could be put to many other uses. The cost would be great, but it would not be useless. It would be effective in its aim and would be of permanent use and a good investment from several points of view, besides giving work to many of our large army of unemployed. Further, the cost to the State of the many lives that would be unnecessarily sacrificed under such conditions as exist at present would by contrast be far greater. Hospital cases would have to be transferred to "safe" areas, but by such a system these would be greatly reduced in numbers. A certain amount of evacuation of civilians would probably still be thought desirable, but under these conditions this could be limited and the

necessary disorganization which this entails restricted accordingly.

We have had a breathing space now, and much might be accomplished before an emergency arose. War is terrible enough at any time, especially modern warfare, but we have a right to expect that everything should be done as far as possible to mitigate these terrors and to prevent all unnecessary sacrifice of life.—I am, etc.,

ARTHUR G. WELLS, F.R.C.S.

Medmenham, Bucks, Nov. 1.

SIR,—There are many pitfalls in thinking unimaginatively of another war in terms of the last, for science has not stood still in the last twenty years. No village in England is now remote from the vastly increased load that a modern bomber can carry at 250 m.p.h. over a range of 1,200 miles. A map of the places which suffered from air raids in the last war shows thirty-three in Norfolk. Thus although a purely agricultural county it was certainly in the danger zone. To-day our village is the same eighteen miles from the sea in distance, but only 4 minutes 13 seconds in time. Our one consolation is that bombs cost money, and we do not expect to be honoured deliberately with any "eggs," but an efficient air force with patrols continuously in the air may well expect to make speedy contact with squadrons of enemy raiders, and hope to bring some down. Thus planes loaded with high explosive, incendiary, or gas bombs may crash even in villages.

While admitting that high explosive bombs will be danger No. 1, gas will rank as No. 2. Thanks to the four wars since 1918, we know that deep shelters are an efficient but expensive counter to high explosive bombs on cities; gas, however, has not been tried out to the same extent as it would be in a totalitarian war between nations with first-class chemical industries. Chlorine was effective at Ypres in 1915 even against disciplined troops when it caught them unprepared and unprotected, and was again effective against the Italians when preceded by arsenical smoke, which penetrated their then inefficient respirators, causing them to vomit and discard their protection. We have been told too often that gas holds no terrors for civilian populations if . . . The public have never realized the implications underlying that qualifying "if" and remained blissfully inert until the crisis.

In July, 1918, "mustard" shells caused 8,000 casualties in one night against trained troops with good respirators because it was not detected. Mustard gas would be without doubt the chemical agent of election should another great war occur. Last time the enemy, being conscientious chemists, used it at the front in a pure state, but we now know that it is as effective in the crude state, of which there would be cheaper and unlimited supplies. Mustard gas hampers even trained troops with the necessity for anti-gas clothing and slow laborious decontamination, but against an untrained and unprotected population its insidious persistence and prolonged after-effects would prove demoralizing, and the nation whose civilian morale cracks first is the loser. Yet Lieutenant-Colonel Cyril Helm (*Journal*, October 29, p. 915) would provide the cities with their admittedly essential bombproof shelters at the expense of village gas-masks! Living as I do in a "remote" village some four minutes from the danger zone, I am thankful indeed that he is not a dictator, although the completeness of our bucolic precautions in the crisis would have surprised many a slumbering city father.—I am, etc.,

Litcham, Norfolk, Oct. 30.

ERIC PUDDY.

A.R.P. and Underground Car Parks for London

SIR,—By extrapolating a graph curve of the numerical increase in recent years of private cars in Great Britain we can obtain ample evidence that unless measures are taken to restrict the daily flow of such vehicles into and out of the metropolitan area the already serious traffic congestion will shortly end in a literal impasse. If private cars on strictly official or trade business or owned by bona fide residents of London were alone allowed inside, and all cars whose occupants were concerned solely with shopping, visiting, theatres, dining, etc., were compelled to be parked outside, say, a six- to eight-mile radius from the Marble Arch, we should not be threatened with an alarming increase of the already existing difficulties of traffic organization. To accommodate prohibited cars commodious underground parking sites would have to be constructed on the principal radiating routes that link up the metropolis with outlying provinces.

The cost of making such parks would admittedly be high, but there would ensue a good return for the initial outlay and cost of upkeep not only financially but in other and more important ways, such as from (1) parking fees and (2) work for the unemployed. The parks, being below ground and well protected overhead, would provide excellent clearing stations for wounded and shelters for thousands of residents evacuating London in the event of air raids. The A.R.P. authorities would have at their disposal and within easy access safe, well lighted and ventilated localities equipped with sanitary arrangements, water supply, and so forth. Adoption of such measures would defeat the disadvantages of a sudden incursion of large numbers of adults and children into country villages with inadequate housing and drainage facilities, and in which neither water nor food supply is capable of meeting the demands of a great number of suddenly introduced extra mouths.—I am, etc.,

CHARLES M. BEADNELL,
Surgeon Rear-Admiral.

Egham, Surrey, Nov. 4.

Food and Nutrition

SIR,—Your leading article in the *Journal* of October 29 (p. 895) on the subject of Crawford and Broadley's book, *The People's Food*, while affording an excellent summary of contents, does not avail itself of the opportunity of supplying a critical estimate. For instance, a general remark could have been made on the sparse treatment of the case of the group who do not spend enough to obtain an adequate diet, an occurrence not to be wholly excused on the grounds of the "advertising" basis of the inquiry, while it could have been pointed out, as was done recently in a review in the *Journal* of another statistical publication, that when one has read the book the addition to one's knowledge is mainly a matter of detail. In fact, in regard to this latter point, the main thesis of the book, relative to the existence of ignorance on dietary subjects and the necessity for education in this respect, has been stressed for years by several writers—for example, Cathcart in the *Journal* of February 27, 1937 (p. 436).

As in other investigations of the same type, there occur here the usual fallacies due to the essential unreliability of the dietary standards, with their blind "shots in the dark" in many instances, or additions, according to taste, opinion, or mere guesswork, to ascertained metabolic requirements, where these exist. The addition of infinitesimally small amounts of certain substances may raise by astronomical figures the numbers in the population alleged to be suffering

from malnutrition, as is well instanced in the table on p. 158 with reference to vitamin A, where the whole population turns out to be undernourished. Failure to include a supply of vitamin D in the dietaries renders the figures for calcium and phosphorus requirements suspect. In the forming of such dietaries the Law of Diminishing Return should receive consideration, and the principle of aiming at accuracy of technique in experimental work only up to the standard of the largest unavoidable experimental error cannot be neglected. The latter canon, adapted to the nutritional sphere, implies that anti-nutritional factors other than of the alimentation variety, some of them of considerable magnitude, little known, and to a marked degree uncontrollable, may swamp not only the terminal fine adjustments in the alimentation field, which, owing to the Law of Diminishing Return, produce proportionately less effect than earlier additions, but even these earlier additions themselves.

While not underestimating the importance of "ignorance" and "education" in the present case—indeed on the contrary—one must point out that "the most urgent problem of all at the present time" would not appear to be, as the authors state on p. 301, "the severely practical task of educating the people of this country in the importance of proper diet," but rather that of supplying an adequate diet to those who have not the means available to procure it.

The main thesis of the authors is stated on p. 161. In all probability, they say, between 20 and 30 million individuals in the population are subsisting on an inadequate diet. Of these, 8 millions are not spending enough to procure it. This leaves, by difference, 12 to 22 millions who, though spending enough on food, are not obtaining an adequate diet. The problem with regard to this latter group, they state, is one for "education"—a difficult matter, as they point out on p. 86, owing to the "lack by the population at large of any spontaneous interest in dietetic subjects."

It is a relatively straightforward matter to obtain statistics regarding the proportion of the population who, while spending sufficient for the purpose, do not obtain an adequate diet, to draw the obvious conclusion that "ignorance" is responsible, and to indicate that "education" is the remedy. Where not enough money is spent to obtain an adequate diet the situation is different. Here three factors—"lack of money," "ignorance," and "luxury purchase"—are involved. The present investigation, though supplying figures for this group as a whole, gives no indication as regards the respective responsibility of these three items within the group. I admit that the procuring of reliable information on this point, since it involves among other things oblique personal criticism, is a difficult matter, as may be instanced by Dr. Neustatter's cautious approach to the subject (*Supplement*, October 1, p. 223).

Suppose, however, that in some way it has been obtained. It is not apparent what general scheme could be framed on it as a basis for ameliorating the situation. "Ignorance," of course, can be met by educative measures, but owing to their inherent basic difference no single plan could at once apply to the "lack of means" and the "luxury-purchasing" categories. In addition, in the actual application of the hypothetical remedy inquiry would be necessary to establish the right of individual cases to partake of the benefits; and this inquiry could be made, once for all, at the outset for the purpose of applying what appears to be the real remedy.

Such considerations go to show the futility of *ad hoc* dietary surveys in this sphere. The fallacy involved in applying statistical laws to individual cases requires no emphasis. In the present instance the application of a national, average, "per caput" cost figure for a dietary to a certain social class or to individual cases from families of varying family composition is entirely without warrant; the climax is reached when it is applied to cases where such psychological factors as "ignorance" and "luxury-purchase" are in evidence. The situation is an individualistic and intensely personal one to which statistical methods are inapplicable. A "locality" factor (reflecting to a considerable degree middleman's costs and profits) is also involved, for owing to varying costs in different districts (vide Dr. Neustatter's price table for

Bermondsey) no general or national average figure for the cost of a dietary in any one social class can be applied to this same class in a district or subdistrict chosen at random.

The only justifiable procedure in the circumstances would appear to be the obvious one. Relevant information regarding income, etc., and local dietary costs having been obtained in regard to an individual presumed to be in need of help towards obtaining an adequate diet, the data are available for deciding whether the individual in question should receive it on the grounds of actual lack of money. If so, it would appear that appropriate action should be taken on the spot not only on humanitarian grounds but also—if the position is accepted that private personal affairs are a public concern to the extent of justifying an inquiry—in order that the work done in carrying out this invidious task (which incidentally a promise of "relief" would render less arduous) should not be wasted. Such cases, indeed, constitute merely a special subsection of unemployment benefit and public assistance—special in the sense that particular care has to be taken that assistance is necessary because of actual lack of money and that, when afforded, it arrives at its true destination.

The details of how such a scheme could be made to function in practice have already been indicated in outline in a previous letter (*Journal*, June 30, p. 257). It is obvious also that in carrying it out data much more reliable than could otherwise be obtained might be collected, which data would have reference not only to alimentation in regard to the state of nutrition but also to other even more important factors having a bearing on it, if such an undertaking did not prove to be too intricately complicated and impracticable.—I am, etc.,

Aberdeen, Oct. 31.

J. P. MCGOWAN.

Safe Childbirth

SIR,—In my book, *Safe Childbirth: The Three Essentials*, I have pointed out that easy labour depends not only on a well-shaped pelvis but also on flexible pelvic joints, and that such flexibility can be attained by correct exercises practised during pregnancy so that the pelvis may expand at the joints (sacro-iliac and pubic symphysis) during the act of birth. For this to occur those postures should be advocated which are adopted instinctively by most women if left to do as they like at the time of confinement—squatting, crouching, kneeling. So far in England I have not found a maternity hospital where I can have patients trained in the correct exercises and postures and confined in the posture best suited to them. To confine crouching a woman whose joints are rigid and whose pelvic floor is contracted is to court disaster—though I find that patients whose joints are flexible (whether naturally or after appropriate exercises) have easier and quicker confinements even if not allowed to assume the postures I advocate for delivery.

My conviction is that neither doctor nor midwife is to blame for our maternal mortality rates, but the mother herself, who must be taught she is an active agent, not a passive sufferer. She must regard herself as an athlete in need of training for her special job, not a poor invalid who must lie down and have the sympathy and prayers of all lest she die of it. Sister Randell of St. Thomas's, with her thirty years' experience, has developed in accordance with this idea a series of suitable ante-natal exercises to increase this natural mobility of the pelvic joints, with other exercises, of an opposite character, to be done during the puerperium to strengthen those muscles which draw

the component parts of the pelvis together. It was necessary to find out what postures seemed most agreeable and natural to the patients during labour. To this end Miss Randell provided the patients with paper and pencil to record their impressions. We have secured some valuable information from this source alone, outstanding being the fact that the posture on back or side was most painful and never willingly assumed. Patients prepared on these lines have easy confinements and regain their normal figure almost at once, as photographs show.—I am, etc.,

London, W.1, Nov. 5.

KATHLEEN VAUGHAN.

Undulant Fever

SIR,—A report of another case of *Brucella abortus* infection may be of interest.

On November 11, 1937, I was called to see a male, aged 32, who gave me a history of having felt sleepy in the afternoons and evenings for a period of about ten days, and, in fact, of having dropped off to sleep while reading the paper on returning from his office. He complained of violent headache and vomiting; his temperature was 102.2° F., his pulse and respiratory rates were correspondingly raised, and his tongue was slightly furred. Clinically I could find no cause for his condition, and made a provisional diagnosis of gastro-intestinal influenza. I treated him symptomatically, prescribing a fluid diet with phenacetin, caffeine, and bismuth carbonate. On the following day his headache and vomiting had ceased and his temperature had dropped to 100° F. After five days his temperature was between 98.4° and 99° F. in the mornings and between 99° and 100° F. in the evenings. The patient said he felt quite well and wanted to get up; this, of course, I refused to allow. At the end of twelve days, on November 23, I observed a few spots—perhaps eight—vaguely resembling rose spots, on the thorax and abdomen. The temperature was still between 99° and 100° F. from 6 p.m. to 10 p.m., but was normal at all other times; the tongue was still slightly furred. I thought of the possibility of one of the enteric group of fevers or undulant fever, and took some blood: the following is a copy of the pathologist's report:

"Negative for *B. typhosus* in dilutions of 1:10, 1:25, 1:50, 1:100, and 1:250. Negative results also obtained for *B. paratyphosus* strains A and B in similar dilutions. With *Brucella abortus* agglutination takes place in dilutions of 1:50, 1:100, 1:500, and 1:1,000, but dilutions of 1:2,500 and 1:5,000 remain negative."

I then tried protein shock therapy with T.A.B. vaccine. The intravenous injection was given at 10 a.m., and by 10 p.m. on the same day the temperature had risen to 105° F. and the pulse rate to 104. The patient was feeling sick, had a violent headache, and was sweating profusely. Next morning his temperature was 97.2° F.; it remained subnormal for two days, then became normal.

The patient made an uninterrupted recovery. He has not suffered any recurrence or relapse although nearly a year has elapsed.—I am, etc.,

J. A. KENNETH DOUGLAS.

Neyland, Pembrokeshire, Nov. 2.

The international committee for instruction and action as regards the protection of the civilian community in time of war, which was set up at Luxembourg on July 4, met on October 28 at the Grand-Ducal Palace, and considered first its three-monthly review, *The Protection of the Civil Population in War*, the first number of which has already been published in Paris. Subcommittees have been constituted to deal with propaganda, diplomacy, military matters, medical treatment, legal questions, civilian defence, and protection of women; the activities of these subcommittees are beginning at once. The next meeting of the international committee will be held in Luxembourg next January.

Medical Notes in Parliament

Civilian Defence

Speaking on November 1 on the appointment of Sir John Anderson the Prime Minister said he would in fact be the Minister for Civilian Defence. He would have charge of air raid precautions and also be responsible for determining arrangements for national voluntary service. Mr. Chamberlain added that the Ministry of Health was in close touch with local authorities, and was responsible for the medical services, including nursing and ambulance provision. Other Departments concerned included the Board of Education, which must marshal children in case of evacuation. It was necessary that the activities of all the different Departments should be co-ordinated, so that each might know beforehand exactly what would be expected of them in an emergency.

On November 1 Mr. Lloyd informed Mr. Simmonds that action had already been taken, on the report of the Anderson Committee on Evacuation, both in the light of the recommendations in the report and of the experience gained during the recent emergency, to examine and prepare in detail evacuation schemes. Steps had been taken before the recent emergency to have ready schemes such as could be operated at once if there were no time for lengthy preparation. Information was given in the Press about such a scheme which had been prepared for London. It was, however, fully recognized that with time for preparation much could be done to improve such schemes, and the detailed work necessary for this purpose was in progress.

The King's Speech

The speech from the Throne outlining the programme of business for Parliament in the new Session was read by His Majesty the King in the House of Lords on November 8. In the course of it the following declarations were made:

The problems of civil defence, including that of the effective utilization of the resources of the nation for national voluntary service, will in future receive the undivided attention of a Minister—the Lord Privy Seal.

My Government will press forward with better housing, both urban and rural, and will proceed with the development of the educational services. They will vigorously continue the campaign for the improvement of the public health, and in particular will submit to you proposals for the earlier and more effective treatment of cancer.

The policy of My Government will continue to be directed to improving conditions in the special areas.

A Bill will be laid before you to amend the penal law dealing, in particular, with young offenders and those who commit repeated offences.

Measures will be laid before you to assist the production, improve the quality, and increase the consumption of milk.

Among the measures which you will be invited to pass will be Bills to amend the law relating to the carrying on of the business of insurance; to amend the Unemployment Insurance Acts; and to raise the amount of the Miners' Welfare Levy, in order to provide additional funds for the building of pithead baths.

A Bill will be submitted to you for the purpose of re-organizing Scottish administration, and centralizing the Government Departments in Edinburgh. Further action will be taken to deal with slums and overcrowding in Scotland, and a measure relating to the financial provision for this purpose will be submitted to you. You will also be invited to consider other Scottish measures, including a Bill for the amendment of the marriage law.

Debate on the King's Speech

During the debate in the House of Lords on November 8 on the motion for an address in reply to the King's Speech Lord STANHOPE gave an assurance that there was no intention on the part of the Government to curtail the social services of the country. He pointed out that in the King's Speech there was a reference to an effort which would be made to deal with cancer, a disease which had replaced tuberculosis as the greatest scourge afflicting mankind. Its seriousness could be gauged from the fact that, according to his information, cancer was responsible for no fewer than 200 deaths a day.

The debate on the address was adjourned until November 10.

IN THE HOUSE OF COMMONS

In the House of Commons, on November 8, the motion for an address of thanks in reply to the King's Speech was moved by Mr. Hely-Hutchinson and seconded by Mr. Markham. Mr. MARKHAM said he was glad to notice the reference to the Government's determination to eradicate cancer. This addition to the social services would be cordially welcomed in all parts of the House. The more effective treatment of cancer could not be carried out by the existing voluntary hospital system, and they would all like to see the most up-to-date methods, in co-operation with the local authorities, to set up adequate staffs and centres for the treatment of this great scourge. More than that, however, the great thing was to eliminate the ignorance, inertia, and fear which were the greatest allies of cancer in this country.

Mr. ATLEE complained that there was nothing in the King's Speech with regard to the social services, that there was no mention of unemployment, and that the Government was equally vague on the question of the special areas. Nothing was said about the condition of the people nor about old age pensions. The Labour Party considered that the foundation of the national strength was in the condition of the people, and that a sound policy of nutrition was a basis of strength; and that that could not be obtained through a means test. The Labour Party welcomed the proposals for the reform of the penal system, the proposals to deal with cancer, and those relating to pithead baths.

GOVERNMENT REPLY

Mr. CHAMBERLAIN said that the Minister of Civilian Defence (the Lord Privy Seal) would give his prompt and undivided attention among other subjects to the evacuation of the civil populations from certain places in times of emergency. The second point which would occupy the Minister's attention would be the provision of adequate shelter accommodation in vulnerable areas. On the subject of national voluntary service a good deal of preliminary planning had been done for the mobilization of the nation's man power, and the Minister would accordingly find a considerable amount of material ready to his hand when he came to formulate his plans under that head.

NO REDUCTION IN SOCIAL SERVICES

With regard to the social services, it was not to be expected that we could at once and at the same time embark on an enormous armament programme, the whole cost of which we were not yet in a position to estimate, and face projects of social improvements which would lay on the taxpayers fresh and impossible burdens. There was no foundation for any suggestion that the Government was contemplating cuts in the existing social services. Nothing that had been said by any Minister gave any foundation for such an accusation, and, as the King's Speech showed, the Government was still making further extensions of the social services. The provisions for public health, the work of housing, and the clearing of slums and providing for overcrowding still went on vigorously. A new proposal mentioned in the King's Speech for making a frontal attack on that perhaps most frightening of all diseases, cancer, would,

he knew, have the approval of all parts of the House. Mr. Attlee had mentioned nutrition, and had spoken as though, because the word did not appear in the King's Speech, it must necessarily be absent from the minds of the Government. It had been in his own mind for many years since a conversation which he had, when he was Minister of Health, with the late Sir Walter Fletcher, who had said to him that by a comparatively small expenditure on teaching people how to feed themselves and their families we could do more to improve the health and physique of the nation even than by the greater efforts which were then being made at the Ministry of Health to improve housing conditions. That statement was so striking that it made a very deep impression on his mind, and as a matter of fact the Minister of Health to-day was engaged on the most far-reaching and comprehensive inquiry into the food habits of the people that had ever been made in this or any other country. Everybody would agree that the more information they had about this subject the better, in order that when they did proceed they might be building on solid ground and be certain they were proceeding on right lines. Referring to agriculture, Mr. Chamberlain said that the most important measure and one of the earliest to be introduced would be the new Milk Bill. The main principle of the Bill was to encourage the consumption of liquid milk, alike in the interests of the farmer and of national health.

The debate was adjourned.

Civil Population in Air Attack

On November 3 Mr. HERBERT MORRISON opened a debate on protection of the civil population in air attack. He said that during the crisis there was a deficiency in the number of gas masks in some localities and some masks were delivered short of vital parts; there were mental hospitals under the care of the London County Council which had not received gas masks to this day. On the subject of hospitals Mr. Morrison said the authorities had to anticipate casualties on a large scale. It was essential that the hospitals organized locally and centrally should trace the movements of the patient from the time he might be damaged in the street, to the first-aid centre, then through the casualty hospital to the base hospital. Ambulances and stretchers were needed. This business was nowhere more vital than in London with its numerous local authorities and hospital authorities. Since 1930 there had been five different inquiries on this subject. Four of these ended without reaching conclusions; finally came a report of the Wilson Committee presented on July 20, 1938. The crisis came in September, and there was no time to finish the plan for the organization of the hospitals. Supreme direction was then undertaken by the Ministry of Health. Fortunately, the London County Council was reasonably prepared and ready with medical reserves and food reserves. In structural precautions in hospitals the council, like other authorities, was not so well prepared, because technical advice was not supplied by the Home Office until June 17, 1938. The story was the same with ambulances. No additional stretchers had been received when the crisis was acute. To supply them was a Government responsibility, and when, under pressure from the London County Council, the Ministry of Health assumed general ambulance responsibility a supply of 4,000 was secured by the end of the crisis week. After the Ministry of Health had taken that responsibility from the Home Office, it issued a circular on September 23 instructing the Metropolitan Borough Councils to earmark ambulances, although it should have known that ambulance organization was the duty of the London County Council under the Air Raid Precautions Act and under the regulations made by the Secretary of State. The boroughs were responsible for first-aid stations, which ought to have been under the Ministry of Health. These were short of medical supplies and of stretchers.

Sir SAMUEL HOARE replied for the Home Office, and pointed out that local authorities had been slow in acting upon Home Office circulars about the reception and distribution of respirators. Eventually the Home Office had to act on its

own initiative, and within a few days over 38,000,000 were distributed.

Mr. R. C. MORRISON said the Ministry of Health was not helpful during the crisis. The local hospitals had no advice or information at all. The voluntary hospital in his constituency (Tottenham, North) was unable to inform the local authority whether it was to be regarded as a base hospital for air raid precautions. The Home Office in the middle of the crisis instructed local authorities that they should distribute to every house in the United Kingdom a booklet principally occupied with information on how to make rooms gas-proof. On the day that booklet was distributed a conference was held at the Ministry of Health, and representatives of voluntary hospitals were there told that "as regards gas-proofing, gas is no longer considered to be a major risk, and it is not thought that any special precautions should be taken."

Sir JOHN ANDERSON, speaking for the first time as Minister responsible for Air Raid Defence, said the question of how to fit in the local authorities would have to be looked at afresh in the light of recent experience.

LONDON VOLUNTARY HOSPITALS DURING THE CRISIS

Colonel NATHAN said he had asked question after question in the House on what was expected of voluntary hospitals, but no information was forthcoming. He was concerned with two voluntary hospitals. One was a special hospital and the other was a great teaching hospital. Both were within the danger area. The special hospital was the Infants Hospital in Vincent Square, and the teaching hospital was Westminster Hospital, where he was chairman of the committee charged with air raid precautions. For months efforts were made to discover what the hospitals were expected to do with their patients, their staffs, and their buildings; what would be their functions in the case of air raids; and where the expense would fall. To none of these inquiries was any answer forthcoming. Only on the day when the Prime Minister's journey to Berchtesgaden was announced were the first steps taken. A meeting of representatives of the teaching hospitals was suddenly summoned at the Ministry of Health, and the Director-General stated that the hospitals emergency service had just been created. Colonel Nathan interposed the remark that Colonel Hebb, Director-General of this emergency system, assisted in the London area by Dr. Dobbie on the London County Council, from that moment gave unstinted service and was of the utmost help. He said the statement made at the meeting in the Ministry was: "Gentlemen, this emergency hospital service has just been created. You must expect bombs to fall on London at any moment. Do the best you can."

No written instruction was ever issued from beginning to end. They were told they must evacuate their hospitals. When they asked how, they were told that ambulances would be provided but that arrangements had only that day been made for conversion of rolling stock and road transports to take stretcher cases and that the services would not be available for three weeks. They were told to increase the amount of hospital accommodation by 30 or 50 per cent., but not a blanket, mattress, or a bedstead had been ordered. When the Ministry of Health was asked what they were going to do they said they were going to commandeer blankets and bedsteads from Harrods, Selfridges, and elsewhere. It was unforgivable that no steps of any kind had been taken, because every casualty resulting from air raids would have to be treated in some hospital. They were told to provide emergency stores, but at the same time that they were asked as voluntary organizations to do all these things they were told that if there was no war the Government would not pay anything for them. They were to make these arrangements at the expense of charitable funds, and if there was a war some unspecified contribution would be made from Government sources.

The two hospitals for which he spoke were able, within a week of the first instructions, to inform the Ministry of Health that they were ready to take emergency cases to an extent greater by 50 per cent. than their ordinary accommodation. They acted upon their own initiative and sought no Treasury consent. They had many difficulties. The Home Office was

unable to provide a sufficiency of gas masks, not only masks for patients but duty masks for the staffs. His interpretation of the Government instructions on gas protection in hospitals was that in a hospital, with the constant traffic of patients in and out, it was impracticable to have complete gas protection. They were advised that special accommodation and gas-proof rooms should be made for cardiac and other chest cases and for the protection of food. They were told that there would be officers from the local mortuary who would deal with the dead. When they asked the local authorities what arrangements they had made for the dead, the reply was that the authorities had no instructions and no information, and no intention, unless instructed, of dealing with the situation. That was an instance of the lack of co-ordination between Government Departments and between the central and local governments.

As regards the special hospital in Vincent Square, originally it was to be a Grade "A" hospital for infants; later, after they were fully equipped to deal with children who might be injured, they were told that this Infants Hospital was to be transformed at once into an adult casualty clearing station. They set about the change, and in a week the hospital was ready to receive, instead of 100 infants, 175 adults. He informed the Ministry of Health that the hospital had operating instruments only for infants and no surgical instruments for adults. He asked where they could get the latter, and how the expense would be borne. The Ministry said it had no instruments and could not help the hospital to get them, and that if the hospital bought them they would not get any grant from the State if there was no war. Thus the hospital was asked to take the whole of the risk, and it took it.

Then there was the question whether men and women should be treated in the same hospital. This was not simple when dealing with casualties resulting from air raids, which would be either gas or surgical casualties. In the ordinary way men went to the men's wards and women to the women's wards, but in a casualty clearing station, with a constant flow of casualties coming in and going out to the base hospitals, that could not be done, and both would have to remain for a time in the out-patient department. The Home Office said that men and women would have to be separated, but he doubted whether this was practicable in the same hospital. Another point was how were casualties to be directed to the various hospitals. It was essential that first-aid stations and hospitals should be under the same general and central direction and administration. It had so far been arranged, on the whole, that no medical officer should be attached to first-aid stations, whereas it was imperative that there should be a medical man in charge of each. It would be impossible for the hospitals to cope with the inrush of casualties unless these had first been sorted into the more and the less serious cases by some responsible person. He hoped to have an opportunity of discussing with the Minister some of the difficulties with which hospitals were confronted.

Mr. Herbert Morrison's motion was defeated by 355 to 130 and an amendment was carried which, while taking note of existing deficiencies in the system of civilian defence, welcomed the decision of the Government to entrust the system to a Minister appointed for that purpose and to complete with the utmost speed the measures necessary to provide for the country's need. This amendment was carried without a division.

Answering, on November 3, questions about air raid precautions, Mr. GEOFFREY LLOYD said contracts for the manufacture of 45,000,000 civilian respirators had been made. Approximately 4,000,000 civilian respirators had been issued to the metropolitan boroughs and the city of London, and had been distributed to the public. The instructions issued by this country about methods of protection against gas remained unaltered.

Undulant Fever in Great Britain

Mr. W. S. LIDDALL asked on November 3 the number of human cases of undulant fever arising in Great Britain attributable to bovine infection through milk or meat in each

of the past ten years, and what measures were taken to reduce the risk of human infection by the group of *Brucella* organisms. Dr. ELLIOT, in reply, said undulant fever was not a generally notifiable disease and statistics of its incidence were not available. Estimates had been made by responsible investigators that there might be some 400 or 500 cases per annum in this country. The importance of all measures to ensure the cleanliness and safety of milk in order to avoid risk from this and other milk-borne diseases had frequently been emphasized by the Ministry of Health. Considerable progress in this matter had been made. He had no information to suggest that meat was a source of human infection with this disease.

On the same day Mr. LIDDALL asked what proportion of tested milch cows in Great Britain showed evidence of *Brucella* infection as manifested by agglutination blood tests. Mr. W. S. MORRISON replied that no statistics were available on the proportion of milch cows submitted to the agglutination test which reacted, but the general view was that about 40 per cent. of dairy cows were infected. Where at a routine clinical inspection of a dairy herd, or at a special inspection made following a report from a local authority that suspicion attached to certain milk, a milch cow was found by a veterinary inspector showing clinical signs of the disease, the sale of the milk of such animal was prohibited by Section 5 of the Milk and Dairies (Consolidation) Act, 1915. The problem of contagious abortion in cattle had been under investigation at a number of institutions under the aegis of a committee of the Agricultural Research Council appointed in consultation with the Medical Research Council.

Insurance Practitioners in England and Wales.—On January 1, 1937, 16,812 medical practitioners in England and Wales were under agreement with insurance committees. The total amount paid them from national health insurance funds in respect of the year 1937 was £8,050,108.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

A. M. Barrett, M.B., B.Ch., of Pembroke College has been appointed University Demonstrator in Pathology for three years from October 1, 1938.

At a Congregation held on November 4 the following medical degrees were conferred:

M.D.—L. Foulds, D. W. C. Gawne, G. Rocyn-Jones.
M.B., B.Chir.—*T. J. Fairbank, *G. H. Baines, *T. L. Barbour,
*R. I. C. Bradford, H. W. Adeney.
M.B.—*G. Williams.

The degree of M.A. was conferred on G. D. Channell and F. W. Smith, University Demonstrators in Anatomy.

* By proxy.

UNIVERSITY OF LONDON

Ian M. Macgregor has qualified to receive the Academic Postgraduate Diploma in Public Health.

The Senate on October 19 awarded the degree of Ph.D. in Hygiene and Public Health (non-clinical) to S. Mukhopadhyay.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following scholarships have been awarded for 1938-9:
Sir Owen Roberts Memorial Scholarship: Miss M. V. Teichmann.
A. M. Bird Postgraduate Scholarship in Pathology: Miss N. T. F. Crowley.
Mabel Webb and A. M. Bird Research Scholarship: Miss M. V. Sudds.

Lectures

A course of three lectures on "The Pathogenic Trypanosomes of Africa and the Tsetse Flies (*Glossina*) that Convey Them" will be given at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., by Dr. H. Lyndhurst Duke on Tuesday, Wednesday, and Thursday, November 15, 16, and 17, at 5.30 p.m. At the first lecture
